ANSWER.—A reverse Queckenstedt test derives its designation because pressure is applied from below instead of from above the spinal puncture needle at the third lumbar interspace. This test is done to determine spinal block below the level of the spinal puncture; that is, below the third lumbar segment. The technic is as follows: A usual spinal puncture is done between the third and fourth lumbar interspaces with the patient on his side. A second spinal needle is inserted through the sacral hiatus and extended upward outside the dura (epidural space). After taking the initial pressure reading of the spinal fluid (spinal puncture needle at the level of the third and fourth lumbar interspaces) followed by readings of the pressure after coughing, straining, and light and heavy pressure on the jugular veins, one proceeds to make a study with the needle in the sacral hiatus. From 20 to 50 cc. of sterile physiologic solution of sodium chloride is injected into the epidural space through the needle in the sacral hiatus. If there is no block between the third lumbar and the end of the needle in the epidural space the pressure as measured in the spinal fluid needle will rise and the patient will experience no pain. If, however, there is a block the pressure will not rise or the rise will be slight and the patient will experience some pain in the lumbosacral region. If the latter occurs, one is able to conclude that there is a spinal block.

STATISTICS ON TUBERCULIN TESTING

To the Editor:—Could you tell me approximately how many tuberculin tests are run yearly on children in the United States? Approximately what percentage of the school population receives tuberculin tests? Do you know of any state or city health department that runs routine tuberculin tests in the schools? I am a medical student and am making a study of the field of tuberculin testing. I should appreciate it if you could supply me with this information. If you do not have these statistics available, could you tell me of some agency where I might obtain this information?

J. D. Beatty, Chicago.

ANSWER.—Unfortunately there is no system of recording the number of tuberculin tests administered to children or the results of tests throughout the nation. It has been recommended that children and adults who react to the tuberculin test but present no other abnormality be reported to health departments for the purpose of tracing the infection to the source and also of making adequate periodic examinations of adult tuberculin reactors. So far this has not been generally accepted by state health departments, although there are communities and one or more cities where the health officers encourage the physicians to report the results of all tuberculin tests. Until such a method is adopted throughout the nation it will be impossible to obtain all the data desired.

The Tuberculosis Committee of the American School Health Association compiles as much information as possible each year on tuberculin testing of school children. This is done through the various state tuberculosis associations. The report of this committee for 1935 showed that 1,124,363 children were tested during that year. Since this report was only from the activities of the state tuberculosis associations and their component societies, it could by no means represent the total figure. In the United States the tuberculin test has become a routine. Thus large numbers of tuberculin tests are administered by physicians in their offices which are never reported; in other words, they are used only at the physician's information with reference to the tuberculosis of the person being examined. Tuberculin testing of

human beings is rapidly increasing in popularity and it appears that the time is not far distant when many millions of tests will be administered annually to school children. The current available figures can be obtained from the Tuberculosis Committee of the American School Health Association by addressing Dr. Charles H. Keene, 3335 Main Street, Buffalo.

GAS GANGRENE ANTISERUM IN RUPTURED APPENDICITIS

To the Editor:—What do you think of the administration of Clostridium welchii antiserum to patients found at operation to have a ruptured appendix?

Frank B. Wisner, M.D., Ludlow, Mass.

ANSWER.—The practical importance of Clostridium welchii in patients with a ruptured appendix is uncertain. The development of that infection is rare. The administration of Clostridium welchii antiserum to a patient with a ruptured appendix would probably not be advised. The slight benefits that might possibly accrue from its use would doubtless be more than counterbalanced by sensitization to serum and possible allergic reaction.

HUSH AND MUM DEODORANTS

To the Editor:—Are you in receipt of any reports of the development of cutaneous irritation and lesions in the axilla following the use of such deodorants as Hush and Mum? During the winter I have had several students with enlarged axillary glands and others with eczematous eruptions which apparently followed the application of these preparations.

Helen B. Todd, M.D., Bowling Green, Ohio.

ANSWER.—"Hush Cream" has been reported by one consumer organization to consist essentially of zinc oxide. No further information on it seems available.

"Mum" has been described as consisting essentially of fat, benzoic acid and zinc oxide. There is no evidence available at present to indicate that these preparations ever contained any aluminum or aluminum salts.

No responsibility for dermatitis should be attached to either of these preparations without a careful study of the case, for the only possibility of irritation from them would be a sensitization to the benzoic acid or to the fat in the ointment base, which are both rare occurrences. The observation that enlarged axillary lymph glands are noted following the use of deodorants is interesting but apparently no report of such effects appear in the literature. Application in drugstores for "Hush Liquid Deodorant" was without result except for the answer that its manufacture has probably been discontinued, for the druggist had none in stock. It was said to contain 12.5 per cent of aluminum chloride, which, used unwisely, might cause a dermatitis on any skin.

INHERITANCE OF HUNCHBACK

To the Editor:—In The Journal of May 27 I note that an inquiry is made regarding the inheritance of hunchback, and in the answer it was stated that there was little likelihood of its inheritance. "Hunchback" is the layman's term for a deformity which may be the result of any one of a number of conditions. Tuberculosis or Pott's disease is certainly a common cause of this disorder, and it is known that tuberculosis is not inherited, although the tendency to contract it may be. Poliomyelitis, rickets, organic scoliosis, epiphysitis and many other bone disorders may cause a marked kyphosis. The Marie-Strümpell type of arthritis may cause a gradual rounding of the spine. The accompanying illustration shows a man aged 31 with this disorder who states that his father and two uncles had the same condition, while two of his uncles had no deformity. One brother has no deformity, another had marked rounding of the shoulders and three had moderate rounding. Two of his half sisters were slightly round shouldered and a third half sister was quite round shouldered. Thus in this case the condition seems hereditary.

John W. Ghormley, M.D., Albany, N. Y.

Man with hunchback whose father and two uncles had the same deformity.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, July 8, page 169.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Sept. 11-13. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. *Written*. Various places throughout the United States, Sept. 9. *Oral*. Part II. Philadelphia, Oct. 14-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written*. Various large cities in the country, Oct. 9. *Applications must be received by the Secretary by Sept. 1*. *Oral*. Philadelphia, Nov. 3-4. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written*. Various sections of the United States, Oct. 16 and Feb. 19. Formal application must be received before Aug. 20 for the Oct. examination and on or before Jan. 1 for the Feb. examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination and review of case histories (Part I) for Group B candidates will be held in various cities of the United States and Canada, Dec. 2. Applications for admission to Group B, Part I, examinations must be on file not later than Oct. 4. General oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 6-8. Applications for admission to Group A, Part II examinations must be on file not later than March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).*

AMERICAN BOARD OF OPHTHALMOLOGY: *Written*. April 6. Formal application must be received before January 1. *Oral*. Chicago, Oct. 7 and New York, June 10. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Boston, January. *Applications must be filed on or before Nov. 1*. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Memphis, Nov. 22-23. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlanta, Ga., Dec. 9-11. Sec., Dr. Byrl R. Kirklind, 102-110 Second Avenue S.W., Rochester, Minnesota.

AMERICAN BOARD OF SURGERY: Part I (*Written*). Simultaneously in various centers throughout the United States, Oct. 9. *Applications must be received by the Secretary not later than Aug. 15*. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

Missouri Reciprocity and Endorsement Report

Dr. Harry F. Parker, secretary, State Board of Health of Missouri, reports five physicians licensed by reciprocity and two physicians licensed by endorsement at the meeting held at St. Louis, May 31, 1939. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Northwestern University Medical School.....	(1937)		Tennessee
University of Kansas School of Medicine.....	(1938)		Kansas
University of Nebraska College of Medicine.....	(1903)		Nebraska
University of Tennessee College of Medicine.....	(1937)		Tennessee
Medical College of Virginia.....	(1936)		New Jersey
School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
New York Medical College and Flower Hospital.....	(1936)		N. B. M. Ex.
University of Pennsylvania School of Medicine.....	(1934)		N. B. M. Ex.

Alabama Reciprocity and Endorsement Report

Dr. J. N. Baker, secretary, Alabama State Board of Medical Examiners, reports twenty physicians licensed by reciprocity and four physicians licensed by endorsement from Jan. 12 through June 5, 1939. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Atlanta College of Physicians and Surgeons, Georgia..	(1911)		Georgia
Rush Medical College.....	(1936)		Indiana
Louisiana State University Medical Center.....	(1936)		Georgia
Tulane University of Louisiana School of Medicine.....	(1935)		Mississippi
(1933), (1937, 2) Louisiana			
Johns Hopkins University School of Medicine.....	(1930)		Maryland
Harvard Medical School.....	(1935)		Penna.
Tufts College Medical School.....	(1933)		Illinois
New York University College of Medicine.....	(1936)		New York
Ohio State University College of Medicine.....	(1937)		Ohio
Western Reserve University School of Medicine.....	(1935)		Ohio
Hahnemann Medical College and Hosp. of Philadelphia	(1937)		Maryland

University of Tennessee College of Medicine.....	(1914)		Mississippi
(1935) Tennessee			
Vanderbilt University School of Medicine.....	(1935)		Tennessee
University of Texas School of Medicine.....	(1937)		Texas
Medical College of Virginia.....	(1937)		Virginia
University of Virginia Department of Medicine.....	(1938)		Virginia

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
University of California Medical School.....	(1937)		N. B. M. Ex.
Duke University School of Medicine.....	(1936), (1937)		N. B. M. Ex.
Licentiate of the Royal College of Physicians and of the Royal College of Surgeons, Edinburgh, and of the Royal Faculty of Physicians and Surgeons, Glasgow	(1934)		N. B. M. Ex.

Wyoming February Report

Dr. G. M. Anderson, secretary, Wyoming State Board of Medical Examiners, reports the written examination held at Cheyenne, Feb. 6, 1939. The examination covered eleven subjects and included 100 questions. An average of 75 per cent was required to pass. Two candidates were examined, one of whom passed and one failed. Two applicants were licensed by reciprocity and one applicant was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Jefferson Medical College of Philadelphia.....	(1933)		85
School	FAILED	Year Grad.	Per Cent
Osteopath*			63.6
School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Wisconsin Medical School.....	(1936)		Wisconsin
Osteopath†			Kansas

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Medical Evangelists.....	(1928)		N. B. M. Ex.

* Examined in osteopathy and surgery.
† Licensed to practice osteopathy and surgery.

Puerto Rico March Report

Dr. O. Costa Mandry, secretary, Board of Medical Examiners of Puerto Rico, reports the written and practical examination held at San Juan, March 7, 1939. The examination covered sixteen subjects and included 160 questions. An average of 75 per cent was required to pass. Five candidates were examined, all of whom passed. One physician was licensed by reciprocity. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Bennett College of Eclectic Med. and Surgery, Chicago (1908)			78.2
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1929)		81.8
Université de Montpellier Faculté de Médecine.....	(1936)		79.7
Université de Paris Faculté de Médecine.....	(1937)		79
Université de Lausanne Faculté de Médecine.....	(1936)		80

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Medical College of Virginia	(1932)		New York

Kentucky Reciprocity and Endorsement Report

Dr. A. T. McCormack, secretary, State Board of Health of Kentucky, reports twenty-three physicians licensed by reciprocity and one physician licensed by endorsement from Jan. 18 through June 17, 1939. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Georgia Medical Department.....	(1922)		Georgia
Rush Medical College	(1937)		Illinois
School of Medicine of the Division of the Biological Sciences	(1936)		Ohio
State University of Iowa College of Medicine.....	(1935)		Iowa
University of Louisville Medical Department.....	(1910)		Tennessee
University of Louisville School of Medicine.....	(1937)		W. Virginia
Tulane University of Louisiana School of Medicine.....	(1935)		Louisiana
Johns Hopkins University School of Medicine.....	(1932)		Maryland
St. Louis University School of Medicine.....	(1928)		Missouri
University of Nebraska College of Medicine.....	(1933)		Nebraska
Duke University School of Medicine.....	(1933)		Arizona
Eclectic Medical College, Cincinnati.....	(1938)		Ohio
University of Cincinnati College of Medicine (1921), (1936, 2), (1938, 2) Ohio			
University of Tennessee College of Medicine.....	(1932)		Oklahoma
(1935) Tennessee			
Vanderbilt Univ. School of Medicine (1924), (1931), (1937)			Tennessee
Medical College of Virginia.....	(1938)		Virginia

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Medical Evangelists.....	(1938)		N. B. M. Ex.

Book Notices

Alcohol in Moderation and Excess: A Study of the Effects of the Use of Alcohol on the Human System. By J. A. Waddell, M.D., Professor of Pharmacology, Materia Medica and Toxicology, Medical Department, University of Virginia, Charlottesville, and H. B. Haag, M.D., Professor of Pharmacology, Medical College of Virginia, Richmond. In collaboration with Committees from the Faculties of the State-Supported Medical Schools of Virginia. Cloth. Price, \$1. Pp. 184, with 32 illustrations. Richmond, Virginia: William Byrd Press, Inc., 1938.

This volume on the effects of alcohol on the human system was prepared by members of the faculties of the medical schools of the two state supported universities of Virginia at the express direction of the general assembly of that state. The text and illustrations clearly and judiciously summarize for the benefit of teachers and other especially intelligent laymen available information regarding the effects of alcohol. Further simplification, explanation, interpretation and popular illustration would be necessary to bring the material within the range of the average reader or school child. "A moderate drinker" is defined as "a person who does not consume a sufficient quantity to noticeably affect his behavior or alter his reflexes. It corresponds to about 0.01% in the blood." The consumption of 1 ounce (30 cc.) of whisky or one bottle of beer, suggested for such drinkers, although only a third of "Anstie's limit," would, according to Grehant's rule, yield several times the level of alcohol in the blood designated in persons without increased tolerance. For such "moderate drinkers" most of the recognized ill effects of alcohol in excess are questioned, although "it is dangerous to operate a car after one has been drinking, even in moderation." The ill effects of alcohol in excess, making its drinker "a menace to himself and to others," are demonstrated, in spite of the unsettled state of certain questions. The social, moral, political and economic aspects of the alcohol are avoided, and the medical aspects particularly are presented.

Das C-Vitamin-Problem in der menschlichen Ernährung. Von Universitätsprofessor Dr. med. et phil. Georg von Wendt. Unter Mitwirkung von Universitätsprofessor Hofrat Dr. Wilhelm Müller-Lenhartz. Boards. Price, 2.50 marks. Pp. 70, with one illustration. Leipzig: Georg Thieme, 1939.

Professor Wendt of Helsingfors is well known for his classic contributions to the knowledge of mineral metabolism. In the present volume he has collaborated with Professor Müller-Lenhartz of Leipzig to discuss various phases of the problem of vitamin C in nutrition. There are five chapters in addition to the foreword. These discuss the nature of vitamin C, the determination of vitamin C and vitamin C requirements, the vitamin C requirements of man and the actual vitamin C intake. The authors point out that the vitamin C intake of people in northern Europe is variable but usually low. During the summer months it increases of course, because of the greater consumption of fresh fruits and vegetables. Various foods are tabulated as sources of vitamin C. It is apparent from the data provided that none of the foods are as rich as leaves in this vitamin. The authors state as their opinion that increasing the vitamin C intake will be found useful in decreasing the incidence of endemic goiter and of tuberculosis.

Cholesterol Content of the Red Blood Cells in Man. By Georg C. Brun. Translation from Danish by Hans Andersen, M.D. Denne Afhandling er af det lægevidenskabelige Fakultet antaget til offentlig at forsvares for den medicinske Doktorgrad, København. Paper. Pp. 237, with 11 illustrations. Copenhagen: NYT Nordisk Forlag, Arnold Busck; London: H. K. Lewis & Co., Ltd., 1939.

To research workers and clinicians this book presents in extreme detail the author's investigations on the significance of the cholesterol content of the red blood cells in man. An excellent review of previous work is given together with a criticism of existing analytic procedures. The author has worked out a modified method which is apparently reliable and which is presented in such detail as to be easily followed by any worker in this field. The fact is demonstrated that, in heparinized blood, lipid extracts will usually be incomplete unless the hematocrit value is reduced by dilution. It is pointed out that previous values for the cholesterol content of the red cells in man are at extreme variance because of the use of unreliable analytic procedures. Hence the author has established normal values

for fifty-eight subjects and treated the data statistically. Normal values as they vary during a month are given as well as the diurnal variation in normal man on an ordinary diet. The observation is made that no change takes place during the day or during several days, including the postabsorption period following meals. These values obviously differ from the plasma values. Finally, studies were carried out on patients to determine whether or not a variation might be observed which could be used in a diagnostic or prognostic way. A group of nonjaundiced cancer patients were studied and compared with a group of jaundiced patients with the observation that it was not practical to demonstrate any relation between the increased cholesterol content of the red blood cells in the jaundiced patient with cancer and some definite feature of the disease in question. In every case, irrespective of the cause of the jaundice, there was an increase in the cholesterol content of the red blood cells, and the suggestion was made that this might be ascribed to the jaundice itself and not to any parenchymatous changes in the liver. There appeared to be no relation between the increase of red cell cholesterol and the site of the cancer in the organism. Tables, charts and case reports present all the data in minute detail. This work represents an extremely valuable addition to the question of lipid metabolism in disease, and because the work was so well controlled and is presented in such detail it should be of value to research workers in this field.

The Distribution of Leucocytes in the Vascular System. By Gert Vejens. Inaugural Dissertation, Upsala. Published in Acta Pathologica et Microbiologica Scandinavica as Supplementum XXXIII, 1938. Paper. Pp. 239, with 54 illustrations. Upsala: Almqvist & Wiksells Boktryckeri-A.B., 1938.

In the author's original research on the distribution of the white blood corpuscles within the vascular system the neutrophils and eosinophils but not the lymphocytes were observed to become adherent to the walls of paracapillary veins under certain conditions. Paracapillary vessels are defined as vessels from 0.02 to 0.30 mm. in diameter. A decrease in the velocity of blood flow and an increase in the fibrinogen content of the blood favor this accumulation of leukocytes in the paracapillary veins. Increasing the velocity of the blood flow or decreasing the fibrinogen content may permit release of these leukocytes again. Experimental evidence is presented to indicate that the marginal position of the leukocytes is due to aggregation of the erythrocytes by the factors which tend to produce a rapid sedimentation rate and to the hydrodynamics of the circulation in vessels of this diameter. The author believes that this explains the inaccuracies of counts done on blood obtained by puncture of the skin and the sudden fluctuations in counts affecting chiefly the cells of the granulocyte series, which are termed pseudoleukopenias and pseudoleukocytoses. The book should prove of interest to any one concerned with the physiologic basis of alterations in the leukocyte and red cell counts in the blood. The studies lend further support to the accumulating evidence that hematologic studies of blood obtained from the vein are more accurate than those made on blood obtained by puncture of the ear or finger.

Short-Wave Therapy: The Medical Uses of Electrical High Frequencies. By Dr. Erwin Schliephake, Dozent at the University of Glessen. With foreword by Elkin P. Cumberbatch, M.A., M.B., B.Ch. Authorized English translation by R. King Brown, B.A., M.D., D.P.H., from the third German edition. Second English edition. Cloth. Price, 21s. Pp. 296, with 148 illustrations. London: Actinic Press, Ltd., 1938.

This English translation of Schliephake's third German edition not only is increased in size but contains a technical contribution by Rhode and an index, both of which were omitted in the first translation. Schliephake's concept that short wave therapy, in which he is an acknowledged pioneer, is a method entirely independent of classic diathermy, is not shared by many other authorities. This concept perhaps explains his rather acrimonious attitude of denying particular credit to the epochal labors of the French savant d'Arsonval in the face of the historical fact that without his fundamental labors in the field of electrophysiology there would be neither diathermy nor short wave therapy. In a foreword by Cumberbatch is presented the conservative attitude of British workers, who hold the pragmatic view that deep heating is the distinctive feature of this measure of physical therapy, but at the same time he leaves a loophole for the admission of a selective action of the current on "colloidal molecules and molecular complexes." It is somewhat

astonishing that Cumberbatch laments the lack of means to measure doses exactly, when as a matter of fact facilities for dosimetry have been created, as should have been evident to him from the literature.

The text proper reveals an undesirable effort to reproduce the German idiom too literally, which is attained at the expense of good English diction and stylistic fluency. There is also a certain looseness about some data and their chronology. Thus in the mention of the labors of Gosset, Gutmann and Lakhowsky, the name of their co-worker Magrou is conspicuous by its absence, while the date of their publication is given as 1934, when as a matter of fact it appeared a decade before. Even the title of Schliephake is still listed as dozent, when the German original shows him to have been promoted to the titular grade of professor.

In spite of these shortcomings, omissions and errors, the present edition is more informative than its predecessor, with the contents manifesting better organization. While it does not fully measure up to the standard set by several publications on this subject in English, the circumstance that it reflects the latest ideas of Schliephake renders the volume of considerable interest to students of short wave diathermy.

Avian Tuberculosis Infections. By William H. Feldman, D.V.M., M.S., Associate in Division of Experimental Medicine, Institute of Experimental Medicine, Rochester, Minn. Cloth. Price, \$7. Pp. 483, with 109 illustrations. Baltimore: Williams & Wilkins Company, 1938.

This book is written by one who has much first hand knowledge of the subject. He has done a great deal of scientific and practical work and published many articles. Indeed, most of the illustrations are from his own work. The book fills a great need. Prior to its appearance there was much confusion in the minds of many persons concerning the significance of the avian type of tubercle bacillus. The literature was so voluminous that only a few persons had time to read it and screen out the important facts. Dr. Feldman has brought together all the important information with a long list of references at the end of each chapter. Thus there is available in this volume all that is definitely known about avian tuberculous infections.

Most readers will be amazed to find that the chickens of this nation are valued at \$200,000,000 and that the chicken industry represents an annual value of nearly \$2,000,000,000. The disease of chickens which is most widespread and one of the most important economically is tuberculosis.

In chapter I a splendid historical sketch is presented concerning our knowledge of the avian type of tuberculosis, with such facts as the discovery by Rivolta in 1889 of a difference between bovine tuberculosis and tuberculosis in chickens. Chapter II is devoted to the biologic characteristics of the avian type of tubercle bacillus. In this chapter alone 167 references are given.

Under diagnosis Dr. Feldman says: "The method of choice for determining the presence of tuberculosis in the living chicken is the intradermal tuberculin test. The specificity of the test can quickly be determined by necropsy." Excellent chapters are included on the pathologic anatomy and experimental tuberculosis in chickens. In the chapter on pathogenicity of avian tubercle bacilli for fowl other than chickens, the author points out that turkeys often contract the disease, in most instances from infected chickens. Parrots frequently acquire tuberculosis, in most cases from the human type of bacillus although at times from the bovine and avian types. Waterfowl, such as ducks, geese and swans, rarely become tuberculous.

In the chapter on pathogenicity of avian tubercle bacilli for cattle and swine the author points out that cattle will become sensitive to tuberculosis after exposure to tuberculous chickens, although such sensitivity is transitory and dependent on continuation of the exposure. Under ordinary conditions of natural exposure, however, avian tubercle bacilli have but limited pathogenicity for cattle. Although swine are infected by human and bovine types of tubercle bacilli, the avian type of infection is by far the most common in this country, where the losses from tuberculosis caused by avian tubercle bacilli in swine approximate \$2,000,000 annually.

Feldman has definitely settled the controversy over the pathogenicity of avian tubercle bacilli for human beings. He has assembled all the reports possible of cases of avian tuberculosis in man from the world's literature and has presented them in

considerable detail in chapter XI. Analysis of the data in thirty-seven such cases exclusive of instances of Hodgkin's disease indicates that in only thirteen were the data sufficiently convincing to establish the presence of the avian tubercle bacillus with reasonable certainty. In approximately fifty cases of Hodgkin's disease in which attempts had been made to demonstrate avian tubercle bacilli, no satisfactory proof was found that this disease is related etiologically to avian tuberculosis. Feldman suggests that the human body has a formidable resistance to the avian type of tubercle bacillus and that therefore it is only the exceptional individual who becomes infected with this organism. For transmission to human beings Feldman believes the more likely sources are eggs from tuberculous chickens, carcasses of tuberculous swine and poultry and contaminated milk.

Chapter XII is devoted to tuberculin and the tuberculin test. In testing chickens a 50 per cent solution of avian tuberculin is injected intracutaneously into the wattle. Only 2 or 3 per cent of the chickens which react to this test do not show gross lesions at necropsy. Feldman expresses the opinion that inability to find the lesions does not prove their absence, since some may be so small that they are not seen with the naked eye. He says: "If a tuberculin of high potency is used and the injections are made properly, characteristically positive reactions are highly specific and, until proved otherwise, indicate a tuberculin sensitivity induced by tubercle bacilli regardless of whether or not morbid changes can be found." Emphasis is placed on the fact that tuberculin made from the avian type of tubercle bacillus results in more reactions when the animal is infected with avian bacilli than when tuberculin is made from the mammalian type of tubercle bacilli. Therefore avian tuberculin should always be used for testing chickens. Feldman's personal experiences have convinced him that acid-fast bacteria other than those which are pathogenic for mammals or fowl are not likely to produce a recognizable sensitivity to tuberculin in chickens.

In the final chapter, devoted to the dissemination and control of avian tuberculosis, the author states that, even though only a few authentic cases of avian tuberculosis in man have been reported, the subject is not a closed one and further investigations are indicated. Every possible attempt should be made to eradicate the disease from chickens, which in turn would quickly lead to the control of the disease in swine. Various methods of eradicating the disease from chickens are described. Under the subject of vaccination with B C G he says: "As a means of suppressing tuberculosis among chickens it is obvious that vaccination cannot be recommended."

Since the public is rapidly becoming interested in tuberculosis and the physician is frequently asked questions, it behooves him to be informed or have readily available information on the various types of tubercle bacilli and the disease they cause in various animals and man. This information and much more is to be found in Feldman's book; therefore it should become a part of every physician's library.

La ponction sternale: Procédé de diagnostic cytologique. Par P. Emile-Well, médecin des hôpitaux de Paris, et Suzanne Perliès, chef de laboratoire à l'Hôpital Tenon. Paper. Price, 75 francs. Pp. 183, with 25 illustrations. Paris: Masson & Cie, 1938.

The authors have previously published a creditable monograph on splenic puncture, and this treatise is concerned exclusively with sternal puncture. They point out, however, that the employment of sternal puncture without examination of other hemopoietic centers may give an incomplete picture in many diseases. The practical and scientific value of sternal puncture is clearly indicated. The introductory chapter is concerned with the technic of sternal puncture and methods of staining the aspirated material. The next chapter deals with the cells which compose the myelogram. This chapter is beautifully illustrated with three full page colored plates. The second part of the monograph deals with the pathologic myelogram in disorders of the blood-forming organs, infections, tumors and granulomas. Concise chapters deal with the observations made by sternal puncture in conditions associated with hepatomegalies, splenomegalies and adenopathies. The monograph is concisely written and well edited. It is beautifully illustrated with colored and black and white illustrations. A concise but adequate bibliography is appended.

Accidents du travail: Accidents de droit commun, invalidités de guerre, maladies professionnelles. Guide pour l'évaluation des incapacités. Par Léon Imbert. Avec la collaboration du Dr. Jean Sédan, ophthalmologiste des hôpitaux. Third edition. Paper. Price, 80 francs. Pp. 544, with 84 illustrations. Paris: Masson & Cie, 1939.

Primarily this publication represents a guide for the evaluation of disability after industrial accidents. Emphasis is placed on the contention that industrial accidents present special surgical features unlike those characterizing the surgery of warfare or the surgery of automobile accidents. A large portion of this book well portrays the unusual medical, surgical and legal features of industrial accidents, together with the industrial aspects of arthritis, heart disease, diarrhea, goiter and venereal diseases. While the subtitle suggests that occupational diseases are embraced, only meager presentations occur, so that the book cannot be sponsored as representing adequate coverage of trade diseases. Its chief worth is in relation to industrial fractures, amputations, mutilations, paralyses and injuries of tendons and muscles. Various sections are devoted to laws, decrees, expert testimony and preparation of reports, all of which would be valuable in French courts and in French insurance matters but are of restricted application in the United States. Apparently because of poor proof reading and organization, chapter headings appearing in the text do not coincide with statements appearing in the table of contents.

Chemie und Technik der Gegenwart. Herausgegeben von Dr. H. Carlsohn, Professor an der Universität Leipzig. Band XX: Vitamine und Hormone und ihre technische Darstellung. Teil 2: Darstellung von Vitaminpräparaten. Von Dr. Franz Seltz. Boards. Price, 10 marks. Pp. 205. Leipzig: S. Hirzel, 1939.

This book is a brief compilation of the chemistry of the important vitamins from the point of view of the pharmaceutical manufacturer. Various preparations of importance are described, with the methods of manufacture or synthesis and fairly complete citation of the patent literature. For persons interested in this field the volume will be indispensable. The vitamins discussed include A, carotene, D, E, K, B₁, B₂, other factors of the B complex, C and H. There is also a discussion of vitamin rich preparations and vitamin containing foods, accompanied by brief descriptions of important patents covering the preparations or processes.

Studien über das Vitamin A beim Menschen. Von Torsten Lindqvist, aus der medizinischen Klinik des Universitätskrankenhauses zu Uppsala. Acta medica Scandinavica, Supplementum XCVII. Paper. Pp. 262; 52. Uppsala: Appelbergs Boktryckeriaktiebolag, 1938.

The author has made an extensive study of vitamin A in relation to human nutrition, and the present volume provides an account of these investigations. The first portion of the book includes a discussion of the chemistry of vitamin A and methods for the determination of vitamin A and of carotene. The account of the investigation includes chapters about (1) introduction and statement of the problem, (2) night blindness as a sign of vitamin A deficiency, (3) review of investigations of night blindness in large groups, (4) the present investigation, (5) statistical methods, (6) methods and review of earlier investigations on the assimilation of carotenoids and vitamin A in the blood, (7) investigation on the assimilation of carotenoids and vitamin A in the blood serum, (8) relationship between the threshold of light perception and the vitamin A content of the serum, (9) relationship between the vitamin A content of the serum and minimum distinguishable light, (10) vitamin A in the serum of persons with high intakes of vitamin A, (11) the vitamin A content of blood as a measure for establishing vitamin A standards of an individual or groups and (12) review of various methods for estimating the vitamin A requirements of man.

The second part describes an investigation of the importance of vitamin A in various diseases and includes chapters about (13) a foreword to the second portion of the book, (14) infectious diseases, (15) diseases of the digestive system, (16) diseases of the liver, (17) endocrine disturbances, (18) disorders of the kidneys, (19) vitamin A in the urine, (20) the estimation of carotenoids and vitamin A in the liver and total cholesterol in the serum and (21) summary. There is a complete bibliography.

The third part of the monograph provides tables of values observed in different cases. A total of 380 persons were examined. In general it was concluded that in persons with

night blindness the carotenoid content of the blood serum ranges from about 4 to 38 micrograms per hundred cubic centimeters. The vitamin A content, in terms of international units per hundred cubic centimeters, ranges from about 40 to 239. In 291 patients without defects in light adaptation and in twenty-five healthy persons the carotenoid content ranged from 6 to 118 and from 22 to 114 micrograms per hundred cubic centimeters respectively. The vitamin A content of the blood serum in terms of international units per hundred cubic centimeters ranged from 69 to 548 for the patients and from 138 to 347 for the healthy persons. During the infectious diseases the values for both carotenoids and vitamin A in the blood serum were low.

Verständliche Wissenschaft. Band XXXIX: Nahrung und Ernährung: Altbekanntes und Neuerforschtes vom Essen. Von Dr. Hans Glatzel, Dozent an der Christian-Albrecht-Universität in Kiel. Cloth. Price, 4.80 marks. Pp. 256, with 25 illustrations. Berlin: Julius Springer, 1939.

Although it is an elementary account of the old and new knowledge of foods, this book contains a tremendous amount of information. There is a brief presentation of the principles of nutrition followed by a discussion of the various components of the diet. The book contains a brief discussion of foods and an account in a philosophic vein of the changing diet in Germany during the last hundred years. The brevity of the book is accomplished in part by an adaptation of the question and answer style of discussion, many of the paragraphs consisting of a question and the answer in the light of existing knowledge. The numerous illustrations provide interesting comparisons of the composition of different types of food and other items. The charts are made more forceful by illustrations. Thus in the chart showing the variation of the vitamin A content of cow's milk there is placed along the abscissa at the bottom various diagrams showing a cow in a stall during the winter months and then at pasture during spring and summer, when the vitamin A content of the milk is increased. A graph is introduced to show the decrease of vitamin C content in the cooking of cabbage, and there are drawings of cabbage being cooked in a pot to accompany the chart. To show the differences in the length of time that certain types of food remain in the stomach, various articles of food are pictured with the figure of a clock to show that each is ingested at the same time. Below each food there is another clock showing when that food would be eliminated from the stomach. The discussion of the food of man is prefaced by an illustration of the structure of the teeth of typical carnivorous and vegetarian animals as compared with the teeth of man. An interesting chart shows the relative intakes of different peoples as compiled by the League of Nations. There is also a chart showing a comparison of home produced and imported foods consumed in present day Germany. It is interesting to note from this graph that nearly all the sugar used in Germany is obtained from within its own boundary, probably as beet sugar. There are at the end of the volume a brief glossary of terms and also a few references to the literature on the subject of foods and nutrition.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Chronic Lead Poisoning a Compensable Accident; Accident Defined.—The claimant was employed by the defendant, the Creston Auto Company, as an automobile mechanic. In that capacity he often had occasion to use a blowtorch, operated by gasoline. Through carelessness or inadvertence, tetra-ethyl gasoline, which contains lead, was used in the torch instead of white or plain gasoline, which is free from lead. As a result, the torch gave off toxic fumes. The claimant suffered from growing weakness, pains and other disabilities and on many occasions, because of sickness, had to be carried from the place of his employment. After about two years he was compelled to discontinue work, and it was recognized that he was suffering from lead poisoning. He claimed compensation under the Iowa workmen's compensa-

tion act but it was denied by the industrial commissioner. On appeal to the district court, Union County, the judgment of the industrial commissioner was set aside, the claimant was held entitled to compensation and the case was referred back to the commissioner for the purpose of determining the amount of compensation to be paid. Thereupon the employer and his insurance carrier appealed to the Supreme Court of Iowa.

Admitting that the findings of the industrial commissioner on disputed questions of fact, in the absence of fraud, were binding on the court, the court pointed out that the commissioner in making his decision had expressly avoided questions of fact and had predicated his conclusions entirely on the proposition that lead poisoning was an occupational disease and as such expressly excluded from the coverage of the workmen's compensation law. The industrial commissioner had pointed out, too, that the claimant proved no injury on any particular day but had made it manifest that disability accumulated gradually over a considerable period, without anything happening in the way of an accident or injury at any particular time. The trial court, however, in reversing the judgment of the industrial commissioner, pointed out that the claimant was engaged as an automobile mechanic. As an automobile mechanic he was naturally and ordinarily exposed to certain common hazards of his occupation, as, for instance, to poisoning by carbon monoxide. If his claim were based on such a hazard, he would be seeking compensation for an occupational disease. It was based, however, on circumstances outside the usual hazards of an automobile mechanic, since he could not have contracted lead poisoning in the ordinary course of his occupation. It was through neglect or oversight or mistake and not as a part of the regular and ordinary business of his employer that he was poisoned, and under such circumstances the poisoning was not an occupational disease. The court quoted with approval from its decision in *Gay v. Hocking Coal Co.*, 184 Iowa 949, 169 N. W. 360, 363:

If the employer fails to provide a reasonably safe place to work, or fails to observe the specific requirements of the statute with respect thereto, and as a result of such neglect the employee is injured, the liability of such employer cannot be avoided by calling such injury an "occupational disease," or by showing that disease of that nature is often the accompaniment or result of such employment, even when all due care has been exercised by the employer. . . . A wrongful injury which operates to destroy or undermine or impair the health of another is no less actionable than is a wrong from which the injured person sustains wounds or bruises or broken bones.

"Without attempting to analyze into just what category the injuries the claimant herein sustained falls," said the Supreme Court, "it is sufficient to say that his injuries were as directly due to injury suffered by him in the course of his employment by the defendant as if he had fallen off a defective ladder or had in any way been given an unsafe place in which to work. That he was gradually stricken and frequently overcome was just as much an injury suffered in the course of his employment as if he had been stricken suddenly by some external and violent means. Whether it be put on the basis of failure to provide a safe place to work, or any other, the defendant inflicted upon its employee an injury for which he should be compensated."

The judgment in favor of the claimant was therefore affirmed. —*Black v. Creston Auto Co. (Iowa)*, 281 N. W. 189.

Malpractice: Absence of License as Evidence of Malpractice; Qualifications of Expert Witnesses; Use of Roentgenograms.—The plaintiff employed an unlicensed chiropractor to improve her general health, to assist her in gaining weight and to make her feel better physically. The chiropractor seems to have attributed her trouble to a displaced vertebra, and when the patient complained of the severity of the treatment the chiropractor explained that the pain was due to the vertebra going back into place. Thereafter the patient sued the chiropractor for malpractice, claiming that she, the chiropractor, was negligent in not using roentgenograms as an aid to diagnosis and that she used undue and unnecessary force in treatment. The trial court directed a verdict for the defendant chiropractor. On appeal, the court of appeals, Hamilton

County, Ohio, reversed the judgment entered in the chiropractor's favor and certified the case to the Supreme Court of Ohio for review.

The fact that the defendant chiropractor was unlicensed, said the Supreme Court, does not of itself warrant any inference that the treatment she administered was negligently or improperly given, but even under such circumstances the plaintiff, in order to recover for malpractice, must show that the injury complained of was due to negligence or unskillfulness. In the trial court the plaintiff sought to prove the chiropractor's malpractice by the testimony of certain nonsectarian physicians, whom she proffered as expert witnesses. These witnesses were not asked as to their knowledge and experience with respect to chiropractic practice and treatment nor did they indicate their knowledge and experience concerning it. On objection by the defendant, the trial court refused to allow them to answer the questions propounded to them. The court of appeals held this to be error, but the Supreme Court concurred in the view of the trial court. When a patient selects a doctor of a recognized school of treatment, said the Supreme Court, he thereby adopts the kind of treatment common to that school and the sufficiency of the skill and diligence with which the patient is treated must be measured by the evidence of witnesses trained and skilled in treatment of that kind. The Supreme Court pointed out, however, that if the criterion by which any witness evaluates the defendant's treatment is the criterion of the defendant's own school of practice, and if the witness is otherwise qualified to testify, the fact that he belongs to another school does not disqualify him.

The trial court erred, however, the Supreme Court held, in directing a verdict in the case, inasmuch as there was conflicting testimony before it with respect to diagnosis. Three physicians called on behalf of the plaintiff, who had examined her subsequent to the chiropractic treatment complained of and had taken roentgenograms, testified that they found "a sacroiliac dislocation or subluxation." The defendant chiropractor claimed that prior to treatment she herself had found a similar condition and that the treatment she administered was directed toward remedying it. There was evidence, however, said the Supreme Court, that the diagnosis made by the defendant after her attention had been called to the roentgenograms was not the diagnosis that she had made prior to that time. Prior to that time she diagnosed the plaintiff's trouble as a displaced vertebra. There was evidence before the trial court, too, that the defendant chiropractor's failure to use roentgenograms resulted in an erroneous diagnosis and that the use of roentgenograms is required because of the difficulty in diagnosing subluxations and dislocations such as those described, unless roentgenograms are used.

The Supreme Court affirmed the judgment of the court of appeals, reversing the judgment of the trial court in favor of the defendant chiropractor.—*Willett v. Rowckamp (Ohio)*, 16 N. E. (2d) 457.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Dextrose and Sucrose Solutions and Heart Disease.—

Ellis and Faulkner observed the changes that took place in the circulation of thirty-one patients with heart disease as well as of five individuals with normal cardiovascular systems during and following the intravenous injection of 100 cc. of a 50 per cent solution of dextrose or sucrose. All the subjects tended to respond in the same general way. The degree or type of heart failure did not apparently influence the response obtained. Slight or no changes in the arterial blood pressure and heart rate occurred. The venous pressure tended to increase moderately during the injection but began to return toward normal immediately on its completion. The increase ranged from 0.5 to 7 cm. of water, with an average of 2.6 cm. for those who received dextrose and 3.5 for those who received sucrose. The plasma volume increased from 3 to 17 per cent (average 13 per cent) within a minute of the completion of the injection. The rise persisted for a varying period of time, but usually after thirty minutes the plasma volume began to fall again and in most cases reached or fell below the control level within an hour. The responses obtained with dextrose and with sucrose were similar. It is clear that the intravenous injection of 100 cc. of a 50 per cent solution of dextrose or sucrose within ten minutes produces a distinct strain on the cardiovascular system. Although the absolute burden is apparently no greater in cardiac patients than in normal persons, such patients have much less reserve for such emergencies. No untoward results were encountered, but it seems that in an occasional case such an extra load on the circulation of a person whose cardiac status is already in precarious balance

may result in serious consequences. Such injections are rational only when it is desired to produce the effect of a markedly hypertonic solution or to introduce sugar parenterally into the body without giving much fluid, but it is not rational to give it with the idea that less strain is produced on the circulation than would result from the injection of a liter of a 5 per cent solution of dextrose given slowly.

Enlarged Hearts in Children.—Kugel points out that only in recent years has it been demonstrated that in many cases what was formerly called "idiopathic hypertrophy" of the heart was in reality associated with congenital malformations, rheumatic fever, glycogen-storage disease, myocardial degeneration and fibrosis. Cases of dilatation and hypertrophy of the heart, associated with myocardial degeneration and fibrosis, constitute the majority of those formerly included under the title of "idiopathic hypertrophy." The term "congenital idiopathic hypertrophy" of the heart is not only undesirable but also confusing. In most instances the cause or nature of the enlargement of the heart in an infant or young child can be determined if the various criteria or diseases are kept in mind. The author states that a study of the cases even as reported in the literature revealed that most of them were not genuine examples of congenital idiopathic hypertrophy of the heart, since either myocardial disease or other factors were found at postmortem examination which could have had a causal relationship to the cardiac enlargement. In 1933 Kugel and Stoloff described seven cases of unusual enlargement of the heart in infants and young children which heretofore might have been regarded as examples of idiopathic hypertrophy. In all instances the clinical picture and the pathologic changes in the myocardium were similar. The chief features of this condition are enlargement of the heart without known cause, an afebrile course, the sudden onset of symptoms, dyspnea and cyanosis and the lack of signs or history suggestive of congenital heart disease, rheumatic fever, diphtheria, infections, anemia or metabolic disturbances. Further investigation of fresh pathologic material with chemical examinations in an additional case confirmed the original impression that this form of cardiomegaly was different from von Gierke's disease and other types of cardiac enlargement.

Virus Pneumonia Secondary to Epidemic Infections.

—Goodpasture and his co-workers describe a specific type of respiratory infection in five infants up to 2½ years of age. The lesions were such as to indicate that, notwithstanding associated bacterial infection, a specific virus determined the fairly distinctive phenomena encountered both grossly and macroscopically. Characteristic intranuclear inclusions, present almost exclusively in epithelial cells of the trachea and bronchi, of their mucous glands and of the alveoli, were an essential detail; epithelial necrosis, ulceration of the tracheal and bronchial mucosa and interstitial pneumonia followed, contributing a peculiar architecture to the lesions. The first instance of this sort that the authors encountered occurred in 1931, following measles; in this case the effects of the virus infection were mild. The next case occurred in 1936 in an infant 2 weeks old who had no history of previous infection; the remaining three

cases occurred in the early spring of 1938 during an epidemic of measles and whooping cough. In two of these the condition followed measles, and in one clinical whooping cough. The authors were not able to cultivate *Haemophilus pertussis* from the lungs or to demonstrate lesions of whooping cough at necropsy in this last case. The infection is severe and can lead to fatal pneumonia in infants, if not primarily, at least by laying the foundation for bacterial invasion. All the cases recorded have come from the central part of Tennessee. In one typical instance the virus infection was recognized by means of frozen sections while fresh tissue was still available for animal inoculation. Rabbits, mice and young opossums showed no evidence of infection after inoculation. A *Macacus rhesus* monkey, having received a suspension of infected lung intratracheally while under ether anesthesia, showed an elevation of temperature on the fourth day; this lasted about twenty-four hours without clinical symptoms and was followed by recovery.

Hereditary Aspects of Dystrophia Myotonica.—Ravin and Waring found twelve cases of dystrophia myotonica among thirty-three examined members of four families. At least four additional cases of the disease could not be investigated. A

table is presented in which most instances to be found in the literature of direct transmission of the disease from parent to child are tabulated. Evidence leads to the conclusion that dystrophia myotonica is transmitted as a single factor dominant but that this dominance is modified by the occurrence of "progressive inheritance." In "progressive inheritance" the onset of the disease is at an earlier age in each succeeding generation (anticipation) and the disease increases in severity in succeeding generations (potentiation). Because of the presence of progressive inheritance the parents of many patients may show little or no signs of the disease, but the disease tends to develop early in the children of patients and so prevents further propagation and the disease dies out in the family. Possible changes in the germinal material which could produce this type of heredity are described. Most studies of sex incidence have shown a preponderance of males but not to a degree suggesting sex linkage. Several of the more complete studies have shown an equal incidence of the sexes. A preponderance of males in smaller series not completed by family investigations probably results from the fact that men are more likely to present themselves for examination because the disease affects their working ability. If a man is affected his economic status becomes such that he is likely to be seen in a clinic, whereas when a woman is affected the economic status of the family is not changed and she is more likely to be seen by a private physician.

Toxicology of Fluorides.—After trying many of the recommended tests for the determination of the fluorine content of blood and tissues and finding them all time consuming or requiring too much material, Gettler and Ellerbrook devised a test that does not have these disadvantages. They state that with their test the presence of abnormal amounts of fluorine can be detected in as little as 10 Gm. or less of tissue, a drop of stomach contents or urine and 5 cc. of blood. Since fluorine is so widely distributed in nature it is present in normal human tissues. In order to establish definitely the true normal fluorine content the authors determined its content in normal human soft tissues, bones, teeth, blood and urine and found that the amounts were small (from 20' to 80 micrograms in 100 Gm. of tissue). There seemed to be no appreciable accumulation of fluorine in any one of the vital organs. The fluorine content of teeth and bones is of the order of from 0.01 to 0.03 per cent. The fluorine content of the urine is the same as that of the tissues. The results of control analyses, to which definitely known quantities of fluorine were added, confirm the accuracy of the method. The fluorine content of several organs in five fatal acute cases of sodium fluoride poisoning was found to be from 0.14 to 1.6 mg. in 100 Gm. of internal organs. The fluorine content of the brain was somewhat smaller than that of any other organ. The fluorine content of the muscles was somewhat lower than the organs but a little higher than the brain. The fluorine content of the urine varied a great deal: in one case it was approximately ten times that of the tissues. The smallest calculated lethal dose of fluorine absorbed into the internal organs in the cases was 104.66 mg. (calculated to a body weighing about 140 pounds). For bodies of different weight the fluorine content of the organs can be calculated by multiplying the combined fluorine content of the liver and the brain by 15. The symptoms of acute fluorine poisoning are immediate severe abdominal pain, with vomiting and purging. Death results from cardiac paralysis and occurs in from one to six hours. Chronic poisoning from small daily doses of sodium fluoride may occur. From 18 to 32 mg. of fluorine per kilogram of weight given daily to dogs for two weeks produced no symptoms except loss of appetite. After somewhat larger amounts, from 50 to 100 mg. per kilogram for several months, the animal walked with difficulty, his back sagged, the hair fell out and the teeth chipped off.

Allergy and the Antirabic Treatment.—To the various types of reactions to the Pasteur treatment Horack adds the report of a patient in whom encephalitis developed without paralysis during the Pasteur treatment. It was believed to be due to an allergic response to the inoculations. As the result of an investigation of sixteen persons who had suffered reactions to the Pasteur treatment an exceedingly high incidence

(87.5 per cent) of allergic disease was observed as compared with a control group (33⅓ per cent) in whom no neuromyolytic accidents occurred. In the control group the allergic individuals suffered much more severe local reactions than the nonallergic individuals. The study suggests that a careful investigation of a patient's allergic background and a determination of his sensitivity to the antirabic vaccine are valuable measures in determining those individuals who may suffer reactions to the treatment. A method of desensitization was successfully employed for three patients who had or developed a marked sensitivity to the antirabic vaccine. A hypothetical analogy is drawn between endophthalmitis phaco-anaphylactica and the unfavorable reactions to the Pasteur treatment. It is suggested that as the result of desensitization, evidenced by the loss of cutaneous sensitivity, a loss of central nervous system sensitivity may also occur. Such a loss of sensitivity would prevent or arrest the development of neuromyolytic accidents associated with the Pasteur treatment.

Neutrophilic Leukocytosis and Cerebral Vascular Accidents.—Townsend and his associates report six cases in which softening or hemorrhage within the brain was associated with the presence of polymorphonuclear neutrophilic leukocytes in the spinal fluid in such numbers as to suggest the diagnosis of meningitis or at least meningeal irritation. They believe that this leukocytosis represents an aseptic reaction of the meninges to the damage within the brain. In none of the cases was there definite clinical or postmortem evidence of an infectious process. Some idea of the frequency of this phenomenon may be deduced from the fact that during the period covered by the authors' observations, approximately nine

months, forty-three patients were admitted to the Baltimore City Hospitals who had had cerebral accidents not more than a week before and in whom signs of meningeal irritation or changes in the spinal fluid were lacking. Their six cases, they state, thus represent an incidence of approximately 12 per cent of the group. It seems to them that in cases of vascular lesions of the brain, whether hemorrhage or thrombosis, the clinical manifestations may be variable, ranging from an acute meningeal syndrome to localizing signs and a history compatible with cerebral vascular accident, with leukocytosis revealed only by lumbar puncture. In view of the experimental work of Cone and Barrera, it seems fair to explain these meningeal reactions on the basis of leukocytic response around the foci of softening or hemorrhage. In three cases in which the authors performed postmortem examination, the necrotic regions showed a varying degree of infiltration with polymorphonuclear leukocytes, mononuclear cells and a small number of wandering phagocytes containing blood pigment. Their first patient, who died early in the course of her illness, showed the greatest degree of infiltration with polymorphonuclear leukocytes. The meningeal reaction in this case was probably augmented by the administration of antimeningococcus serum.

Vitamin C and the Aging Eye.—In the course of routine refraction tests on a number of patients at the Hastings State Hospital during the late summer months of 1937, Bouton observed clouding of the optic media associated with impaired vision. Apparently this was a precursor of senile cataract, a concomitant feature of early cataract or a morbid condition. Various groups of the employee and patient population of the hospital were tested for the twenty-four hour urinary excretion of ascorbic acid, the level of the substance in the blood plasma and the twenty-four hour excretion after 600 mg. of pure ascorbic acid in tablet form was taken orally. The tests were all carried out during the late winter months of 1938. The observations differed among the groups but indicated definite vitamin C deficiency for the patients in general. For a control group of persons not connected with the institution the results corresponded in the main with those given in the literature for normally nourished persons. The described tests were also performed on a special group of patients who presented visual disturbances due apparently to changes in the tissues associated with aging of the eye. These patients were subjected, in addition, to ophthalmoscopic examination and to reading tests. The data indicated an even more marked vitamin C deficiency in this group than among the other institutional patients. Half of these patients were given massive daily doses of ascorbic acid by mouth for eight weeks, while the others received the same medication for four weeks. Determinations of the levels of reduced ascorbic acid in the blood plasma were carried out at regular intervals during treatment and one week after it, in addition to ophthalmoscopic and reading tests. The study indicated improvement of eyesight in 60 per cent of the treated patients, that is in all patients not suffering primarily from senile cataract. Marked improvement sets in within the first two weeks of treatment, if it occurs at all, with slow progression or no further change from then on. Cataracts were apparently not affected by this method of treatment, all improvements being due to clearing of the optic media and apparently to the beneficial effect on the retinal vessels and the head of the optic nerve. Whether the latter observations represented a direct or an indirect action of ascorbic acid is still a matter of conjecture, although reports of recent work indicate that a direct effect is probable.

Action of Sulfanilamide.—From a study of the mode of action of sulfanilamide in vitro and in vivo on the hemolytic streptococcus, Keefer and Rantz present the following conclusions: 1. When sulfanilamide was added to whole defibrinated blood so that the concentration was 7 mg. or more per hundred cubic centimeters there was definite bacteriostasis and in some instances a definite bactericidal effect. 2. A bactericidal effect of sulfanilamide was not seen when it was added to plasma, although bacteriostasis occurred. This bacteriostasis was less striking in plasma than in whole blood. 3. A bactericidal effect with sulfanilamide occurred in blood containing some natural antibodies. Therefore, sulfanilamide may enhance the bactericidal effect of whole blood provided natural antibodies

are present. 4. In the cases in which a bactericidal effect was not demonstrated, a bacteriostatic effect was shown. When the number of organisms was small there was almost complete bacteriostasis; when the inoculum was larger the rate of multiplication was slower and the number of organisms at the end of twenty-four hours was less than in the controls. 5. It appears that antibodies are important in destroying hemolytic streptococci in vitro even in the presence of sulfanilamide. 6. The principal action of sulfanilamide in vitro is to slow the growth of the organism. It has no direct bactericidal effect on any serologic type of hemolytic streptococci.

Blood Sedimentation in Otitis Media.—Hume and Kahn aimed to show the trend of the rate of sedimentation in otitis media and its complications by repeated estimations and to bring out any relation that may exist between the leukocyte count and the sedimentation rate. Eleven cases were studied and there was at least one representative of each of the several types of the disease found in the middle ear and mastoid. In the case of simple uncomplicated acute otitis media the rate of sedimentation remained well within normal limits, despite a comprehensive shift in the blood picture to that of a septic process. When the serous effusion of acute otitis media becomes purulent there is a prompt rise in the sedimentation rate. The blood picture in these cases points only to an acute process. The sedimentation rate, as compared to the relatively rapid change of the blood picture, is slow to return to normal. Apparently the sedimentation rate follows the clinical regression of the pathologic changes in the middle ear. In chronic otitis media with acute exacerbations neither the blood picture nor the sedimentation rate was changed appreciably. This might be explained by fibrosis of the tympanum and mucosa of the middle ear and mastoid process. With fibrosis there is a decrease in vascularity, and with the latter there is less absorption of toxins. This lack of significant change in uncomplicated acute otitis media might be due to the fact that despite the marked congestion of the involved parts there is no actual destruction of tissue. In a case of acute exacerbation of chronic mastoiditis there was a rise in the sedimentation rate, associated with a blood picture indicative of infection. Here there was reason to believe a low grade destructive process was going on. On conservative treatment resolution occurred and the sedimentation rate fell to normal, as did the blood picture. The latter change occurred much more rapidly. In three cases of massive destruction of tissue and necrosis of bone the rate of sedimentation increased markedly after operation and was followed by a more gradual return to normal. This secondary rise may be assumed to be the result of the increased damage to the tissues incident to any surgical procedure. The blood picture in these cases is that of any septic process. In two cases representative of chronic mastoiditis in acute exacerbation only moderate changes in the rate of sedimentation were seen. The authors draw no definite conclusions as regards any correlation between the blood picture and the sedimentation but believe that the blood picture does seem to be more responsive to the acute inflammatory process, while the sedimentation rate appears to give a truer picture of the degree of destruction of tissue.

Sinuses as Foci of Infection in Arthritis.—In 100 cases of infectious arthritis Williams and Slocumb point out that x-ray examination indicated changes in the paranasal sinuses in only forty-two in which the condition might have been

caused by infection. Of the forty-two patients, seventeen related a history suggesting suppurative disease in the paranasal sinuses and four of hay fever or vasomotor rhinitis. Therefore, twenty-one of the forty-two cases presented x-ray evidence and a history of symptoms of rhinitis. Clinical investigation yielded definite evidence of suppurative disease of the paranasal sinuses in twenty, nineteen of which were in the group of forty-two in which positive x-ray evidence was obtained; in one case, in which suppurative involvement of the sphenoid and the posterior ethmoid sinuses was found, the results of x-ray examination of the paranasal sinuses were negative. In seventeen cases in which x-ray evidence of sinusitis was obtained, clinical investigation did not yield evidence of sinusitis and in six cases the examination was reported incomplete. In three cases in the group of twenty in which clinical investigation had yielded evidence of sinusitis, removal of infected teeth or local treatment of the nose apparently eradicated suppurative disease in the paranasal sinuses, but a favorable effect on the course of the arthritis was not observed. In this same group there were two patients with cardiac complications contraindicating operative intervention and three refused surgical intervention. Of the twelve patients with infectious arthritis who were subjected to operation on the paranasal sinuses in an attempt to eradicate a focus of infection, six experienced permanent improvement that might be attributed to the operation, but in four of these six tonsillectomy was also performed at nearly the same time. One other patient experienced transient improvement in arthritic symptoms after operation on the sinuses. The results experienced by these six patients do not support the conclusion that sinusitis is the principal focus of infection in cases of infectious arthritis. Too optimistic an outlook as to the results of this type of therapy should be avoided, although the sinuses should not be ignored as possible foci of infection.

*Platelet Studies in Hemophilia. Following Intravenous Administration of Platelets. Experimental Study on Dogs. T. R. Van Chicago.—p. 840.

Platelet Studies in Health and in Hemophilia.—Lee and Erickson studied the total and differential platelet counts and disintegration rates, with changes in the differential at the end of the disintegration period, of normal men, nonmenstruating women, normal women during menstruation and persons with hemophilia. The majority of the total counts in all groups were between 400 and 600 thousand. Acute colds seemed to cause a definite drop in the count. During menstruation the totals were moderately lowered. When the count was high in normal individuals the percentage of large platelets in the differential was higher, while in the hemophilic patients the proportion of large platelets was definitely decreased. The disintegration rate determinations indicated a 30 per cent destruction as the lower limit of normal. Patients with hemophilia and menstruating women gave a retarded rate. The clotting time was delayed up to twenty minutes during menstruation, the normal with the method used being from ten to twelve minutes. These points establish a similarity between the blood of hemophilia and that of menstruation. Intradermal platelet injections produced a mild reaction in normal persons, whereas a negative reaction was obtained in hemophilia; in patients with chronic idiopathic thrombopenic purpuras the reaction was increased. From one case of aplastic anemia with few platelets a negative reaction was obtained. In the secondary thrombopenias both increased and negative reactions occurred. All reactions became normal, however, when the platelet count became normal. These data indicate that platelet differential counts

and disintegration rates, together with tests of skin sensitivity to platelets, may become an important aid in diagnosis and prognosis.

Hepatic Dysfunction in Renal Lithiasis.—Ezickson determined the hepatic function, by the bromsulphalein test, of thirty-nine persons who have or have had renal or ureteral calculi. In fifteen individuals given 5 mg. of the dye per kilogram of weight 50 per cent of the thirty minute nonfasting specimens showed retention of the dye, ranging from 14 to 60 per cent. There was a 90 per cent retention of the dye, ranging from 13 to 40 per cent, in the thirty minute fasting specimens of persons given 5 mg. of the dye per kilogram of weight. Thirty-four patients were analyzed for vitamin A deficiency and thirty-two (94 per cent) showed a deficiency. The data from this investigation lead the authors to believe that there is a close relationship between hepatic dysfunction, vitamin A deficiency and renal lithiasis. This should open up a new avenue in the study of the pathogenesis of renal calculi.

*Reducing Premature Infant Mortality, with Special Emphasis on Resuscitation. A. V. Stoesser, Minneapolis.—p. 236.

Premature Infant Mortality.—Stoesser discusses the means by which the premature infant mortality was reduced at the Minneapolis General Hospital. The study takes in a period of eight years. The first two days of the infant's life are referred to as the "period of resuscitation." The second period is roughly divided into two phases. The interval from the forty-eighth hour to the tenth day is termed the period of "adaptation to feeding" and from the eleventh day up to the time of discharge the "period of growth and development." During the first and second years of observation a large number of the infants died from bronchopneumonia, otitis media and erysipelas in the period of growth and development. Respiratory infections were prevalent among the personnel of the hospital especially during the winter months of the second year. Rigid isolation technic was introduced and the results were most encouraging. The 27 per cent death rate occurring after the tenth day of life in the second year of observation dropped to 3.5 per cent the following year. There was again an increase of respiratory infections in the fourth year but the death rate rose only to 6.9 per cent. With gradual improvement along simple lines in the physical set-up of the premature nursery there was a consistent fall the following years in the number of infants who died during the period of growth and development. Examination of the records of the infants dying during the period of adaptation showed that many of these babies had a large amount of regurgitation, which was followed in a few days by marked diarrhea. At necropsy, bronchopneumonia was found in a few cases while others gave some evidence of infection in the middle ear. Efforts were made to stop the regurgitation and the diarrhea by concentrating the formulas and by changing to feedings containing a high protein and a low carbohydrate content. The response was poor. A new feeding schedule was adopted. Starting with small amounts for the

smaller premature babies, the food intake was gradually and carefully increased for at least ten days. After this, larger increases in volume were permitted. The majority of the babies adapted themselves to the formula and progress was ultimately good. The mortality rate during the period of adaptation to feeding dropped to a low figure and remained there, but there was no improvement during the first forty-eight hours. Too much attention had been given to the later phases of premature care, and not enough emphasis had been placed on the methods of resuscitation. Many of the premature infants who failed to respond during the first hour of the period of resuscitation had subnormal temperatures. This prompted the construction of a unit or incubator containing a regular bassinet, by means of which the temperature of the infant was kept at the proper level from the moment of birth. The infant was then closely watched and the necessary measures for resuscitation were performed within the unit rather than on the delivery table, where chilling could easily take place. Mucus was removed from the air passages. The head of the bassinet was always lowered from 4 to 6 inches so that the secretions and the mucus in the respiratory passages could escape. For the first hour of life the premature infant was disturbed as little as possible. Then if he appeared to be doing fairly well, he was moved in the incubator to the nursery and weighed. Following this, a rest period of sixteen hours was permitted. No water or food was administered. At the end of this period, excessive amounts of the vernix caseosa were removed with oil and, if the baby's color was good, water and later milk were given in small amounts. Throughout the first forty-eight hours of life the infant was closely observed for cyanotic attacks. The results of these simple measures were fairly good. The mortality rate dropped from 19.1 and 20 per cent in the fifth and sixth years of observation to 12.2 and 14.5 per cent in the seventh and eighth years. The author discusses some of the salient features of present day resuscitation in order to stimulate a more determined and concentrated effort to improve the system of accomplishing normal breathing in the newborn. Although there is still plenty of room for investigative studies, present methods when properly performed can save many infants, especially premature babies. There always will be a certain number of deaths from intracranial hemorrhages, anomalies incompatible with life or marked developmental deficiencies.

Agranulocytic Angina.—Jackson and Tighe discuss the efficacy of various forms of treatment in 390 cases of acute agranulocytic angina reported in the literature since 1933. Only papers giving complete data relative to diagnosis and treatment are considered. The mortality in seventy-five untreated cases was 78 per cent. The mortality of forty-three persons given no specific therapy but receiving more than three days of general hospital care was 70 per cent. The mortality of the 130 persons receiving inadequate amounts of any supposedly specific therapy was 77 per cent. Neither transfusions nor roentgen therapy seemed to alter the mortality rate. Treatment by yellow bone marrow extract, leukocytic cream or adenine sulfate has not been widely enough reported on to permit any accurate conclusions as to their worth. Because of the low mortality in the cases so far reported, these measures deserve further trial. The mortality in the twenty-six cases treated with adequate amounts of liver extract was 62 per cent. The mortality in the eighty-five cases treated with pentnucleotide was 35 per cent. At present it would appear that pentnucleotide in doses of at least 40 cc. a day is the most promising form of therapy in this disease.

Otogenic Nonsuppurative Encephalitis.—Atkinson asserts that, when localizing cerebral signs appear in the course of an adjacent suppurating focus in the skull, the most likely diagnosis is brain abscess but that there are times when exploration reveals no abscess. An area of infection that has not broken down may cause a localized nonsuppurative encephalitis, in which case exploration is not only unnecessary but often dangerous. The condition is more common than is generally appreciated. The author encountered fifteen such cases; the

total reported is twenty-five. As with abscess, the condition is most common in the temporal lobe secondary to ear disease. The pathologic changes of localized nonsuppurative encephalitis are those of localized cerebral infection in general and in essentials are the same as those of inflammation in any part of the body. Orogenic nonsuppurative encephalitis presents the signs of a focal cerebral lesion associated with an active or recent suppurative focus in an ear or nasal sinus. There are three stages of the process. 1. The salient feature of serous encephalitis is the onset with a convulsion, after recovery from which the patient is found to have focal cerebral signs. The attack may be single or it may be repeated. After each attack the focal signs are more marked. In every case a dural lesion, commonly an extradural abscess, is found and treatment of this and of the original focus results in permanent disappearance of focal signs within forty-eight hours. All patients with a suppurating lesion in the skull in whom a convulsion supervenes should be explored without delay in the expectation of finding some dural lesion. 2. Chronic infective encephalitis offers the greatest difficulties in diagnosis. With a nonsuppurating area of encephalitis, headache is apt to be severe and continuous, eyegrounds commonly show slight changes and fever is present. But the sign of greatest value in differential diagnosis is in the spinal fluid; hundreds of polymorphonuclears are found, as against tens of mononuclears in abscess. In encephalitis clinical signs and spinal fluid signs rise and fall together, while when suppuration and localization are present physical signs increase and the spinal fluid signs decrease: the dissociation syndrome emphasized by Borries. 3. Acute infective encephalitis gives a characteristic clinical picture. There is mental excitement, even noisy delirium different from the drowsiness or stupor of an abscess patient; the clinical signs are widespread from an early stage, fever may be high with a corresponding pulse, and the patient rapidly becomes gravely ill; there is often papilledema, and the spinal fluid shows an increased cell count in the hundreds, the greater proportion being lymphocytes, which suggest a nonpyogenic organism. Exploration should be avoided unless a diagnosis can be made by no other means. To incise an area of inflammation before suppuration has occurred is the surest way to provoke it and to spread the infection. But exploration of the focus of infection and of the neighboring dura is incumbent, with appropriate surgical treatment of any lesion found. At the same time a local decompression by free removal of bone should be made. Other positive measures are such as may also be used for a tumor with increased pressure: hypertonic solutions, limitation of fluid intake, catharsis and lumbar punctures. In chronic cases hypertonic solutions are not recommended. Their use may induce a false sense of security, and the improvement in symptoms occurring as an abscess localizes may be ascribed wrongly to the good effects of the sucrose.

Electrothermy and Radiation for Cutaneous Cancer.

—For the last eight years Hathaway and Howard have used a combination of electrothermic destruction and roentgen radiation in the treatment of cutaneous cancer. Of the 183 cases that they were able to check up on by personal observation or questionnaire they find that, if they assume that the nine patients who died of other causes would not have suffered a relapse, there were 175 (95.6 per cent) clinical cures for from one to eight years. The five patients who returned with

recurrence were all retreated and have to date shown no sign of recrudescence. Of the three patients whose deaths were due to cancer, one had refused obviously indicated radical therapy, another had failed to return for a period of two years, and all three had long neglected highly malignant lesions.

Laryngologic Aspect of Hematopoietic Disease.—Shea discusses some of the laryngeal characteristics of the primary blood diseases. The usual initial lesion of granulocytopenia produced in the pharynx consists of a necrotic ulcer of one of the pillars, accompanied by a localizing swelling of the region suggestive of a peritonsillar abscess. The hematopoietic response to a streptococcal infection of the upper part of the respiratory tract and throat should be a polymorphonuclear leukocytosis with a shift to the left of the Schilling hemogram and occasionally the increase will be 20,000 or better. The initial involvement may be a simple surface inflammation of any or all of the mucous linings of the nose and throat. Extension superficially or deep into the glands will be accompanied by edema. The disastrous edema occurs in the larynx and is more dangerous to younger patients. Infants with severe streptococcal infections of the throat frequently require surgical relief. The infection of Vincent's angina seldom changes the blood count, but occasionally there occurs a hemic response to an overwhelming invasion of the organisms of Vincent's. This response is a lymphocytic leukocytosis with a hypogranulocytosis. The lesions in the throat in infectious mononucleosis vary from slight ulcerations to extensive inflammations, and the bacterial study of direct smears and cultures gives no help. The presence of Vincent's organism in the direct smear is common if there is an anaerobic recess, as under a membrane covering a slough. Acute lymphadenitis is a rare disease. The clinical picture of the mouth and throat begins with a simple and innocent looking angina or gingivitis, which is followed by hypertrophy of the lymphoid tissue producing islands throughout the visible surfaces of the mouth and throat. The tongue swells, becomes dry and is coated with dry blood; minute

hemorrhages ooze from the multiple lesions; swallowing becomes difficult and painful and the terminal days are pitiful; as the glands of the neck extensively enlarge, the face becomes swollen. Leukemia may be myeloid or lymphoid and surgical intervention should be avoided during the undiagnosed stage of the disease. It is a good practice to have a routine hemogram of all surgical tonsil patients before operation, so as not to discover after operation an uncontrollable oozing, because one may have been guilty of removing the tonsils of a leukemic patient. The lymphoid tissue of the throat and mouth hypertrophies, especially in the lymphatic type, and as in lymphadenosis islands appear on the gums and other mucoid surfaces and the glands of the neck share in the general glandular enlargement. Paralysis of the cranial nerves is not uncommon, especially of the facial nerves.

Migraine and the Pituitary.—Halloran proposes that migraine is due to swelling of the pituitary gland, which creates compression of the cavernous sinuses resulting in congestion of the whole venous system of the skull. Pressure on the pain papilla within the walls of the dural sinuses creates the headaches. The various components of migraine are thought to be pressure phenomena having their origin in the nerve structures in and about the cavernous sinuses and sella turcica. It is further proposed that ergotamine tartrate (gynergen) decreases the vascular bed of the skull and brain, which in turn relieves the congestion and headache. The depression following migraine is thought to be due to accumulation of metabolites in the sensorium. Thus many mental states may be due to anoxemia of the brain. Further studies are indicated in the use of ergotamine tartrate and oxygen in the treatment of mental ills, acute alcoholism and delirium tremens. A close analogy is suggested between migraine, epilepsy and eclampsia. The periodic attacks of migraine are in keeping with the periodic fluctuations of the pituitary. There are many cases of migraine due to allergy. The author feels that explanation of this may lie in the fact that the anterior lobe of the pituitary is derived from the pouch of Rathke, from which nasal mucosa is derived. The latter is allergic. Hence it is not unlikely that the anterior lobe is an allergic shock tissue and responds to allergens by swelling.

Clinical Uses of Sex-Endocrine Products in Gynecology.—Urdan discusses some of the clinical uses of sex-endocrine products in various gynecologic disorders. Amenorrhea is generally due to failure of the anterior pituitary gland or of the ovary or occasionally to failure of uterine development. Thyroid disturbances, especially hypothyroidism associated with obesity, frequently cause amenorrhea. Insufficient secretion of anterior pituitary gonadotropic substance is the most common cause. Treatment with hypophysial extracts is the method of choice. Estrogen is of use in amenorrhea to combat uterine atrophy and is followed by menstruation in women who have a fair degree of ovarian function. The successful endocrine treatment of most severe cases of amenorrhea will depend on the elaboration of a potent gonad stimulating product. In functional uterine bleeding there is merely an exaggerated proliferative phase of the endometrium with inadequate luteinization and thus the condition is really due to disturbed function of the anterior pituitary gland. Progesterin is used in the treatment of functional hemorrhage, but the treatment is purely substitutive and the effect is temporary. In the evaluation of the problem of functional dysmenorrhea the development, the hormone control and the nervous control of the uterus must be considered along with the constitutional and nervous makeup of the individual. The property of progesterin of overriding the stimulating action of estrogen would indicate its use in dysmenorrhea. Estrogen in dysmenorrhea seems indicated only in those individuals with hypoplastic uteri. The most spectacular results with estrogen are obtained in patients suffering from the symptoms of the artificial or natural menopause. The author's form of therapy, with almost complete relief in all cases, is 4,000 rat units of estradiol benzoate twice a week for from four to eight weeks until the symptoms are controlled. This is followed by emmenin in doses of one teaspoonful daily. The oral method as a rule controls patients suffering recurrences and no hypodermic medication is necessary. The change of the immature epithelium to the adult type of vaginal mucosa and the increased acidity of the vaginal mucosa incident to estrogen medication appear to play an important part in the eradication of gonorrheal vaginitis in children. The author's method of treating senile vaginitis is 2,000 international units of estrogen three times a week for from four to six weeks. Occasionally vaginal suppositories of estrogen are given as supplementary treatment. In functional sterility the gonad stimulating principle is best given in two or three divided doses just prior to the expected ovulation. Estrogen has been used in sterility associated with amenorrhea, hypomenorrhea and in infantile uteri with occasional success. However, the gonad stimulating principles are preferred. The use of progesterin in cases of habitual abortion has a definite experimental background (Corner). When avitaminosis, hypothyroidism, deficient spermatogenesis and systemic diseases are not the causal factors in habitual abortion the use of an endocrine substance is indicated. Of the author's eleven patients who have had two or more spontaneous abortions for which there was no apparent cause, ten have delivered normal infants following the use of corpus luteum extract. The remaining patient aborted at eleven weeks. One patient had a subsequent normal birth without treatment; another was allowed to proceed in her second pregnancy without the extract but developed signs of threatened abortion which were controlled by the use of progesterin. Of thirteen patients with threatened abortion, only four went to term despite the fact that treatment was instituted early. In the other nine cases symptoms continued with subsequent abortion. Treatment in the successful cases was continued through the sixteenth week of pregnancy, one international unit being given twice a week after the symptoms subsided.

Biologic Pregnancy Diagnosis Tests.—Crew compared the biologic pregnancy tests and asserts that the Hogben test (using the toad *Xenopus laevis*) can replace the Friedman rabbit test but not the Aschheim-Zondek mouse test. The toad can give a trustworthy positive result within six to fifteen hours, as compared with the twenty-four to forty-eight hours needed if the rabbit is used. The toad is better than the rabbit for use in those cases in which a definite positive or an emphatic negative is the answer, especially when the result is urgently required. With the present methods of preparation, however, the toad does not give the graded results yielded by the mouse. It may be shown later that differences in the number of eggs extruded are indeed true reflections of corresponding differences in hormone concentration, but for the present the mouse must be retained.

The Sign of the Clavicle.—Among 2,000 mental defective patients Dax and Stewart found sixty-four with congenital syphilis. They reexamined these to determine the incidence of enlargement of the sternal end of the clavicle. Higouménakis has stated that this sign is one of the most common stigmas of congenital syphilis. The clavicles of 1,200 nonsyphilitic patients have been examined as controls. Palpation gives more information as to size and shape than a single roentgenogram. From an analysis of their material the authors differentiated five types of abnormality, two or more of which may be found in the same patient: (1) a generalized enlargement of the sternal end, (2) an exostosis projecting from the inner end of the bone, (3) a roughening of the inner third, (4) a thickening of the posterior surface of the outer third or an enlargement of the middle of the bone and (5) a tubercle at the point of origin of the clavicular head of the sternomastoid muscle. If any of the first three abnormalities were present to a marked degree in a case of congenital syphilis they classed this as a positive result. Minor deformities were found to be common even among normal persons. Nineteen of the sixty-four cases of congenital syphilis show gross abnormality of the inner ends of the clavicles, in the form of general enlargement, exostoses or roughening. The 1,200 controls represented examples of all

degrees of mental disorders. Thirty-nine of the 600 men and twenty-six of the 600 women examined have marked clavicular enlargement similar to that observed in the cases of congenital syphilis. No obvious relation between the hand used and the enlarged clavicle was found to exist in either the patients with congenital syphilis or the control group. Not a single case of congenital syphilis was observed with gross enlargement of the clavicle on the one side that was not accompanied by some degree of deformity on the other. The authors give possible explanations for the difference in their results from those recorded by Higouménakis and others: 1. The sign may be produced in its fully developed form only when the patient has done manual labor. If this is so, the majority of their patients are incapable of sustained work. 2. All the controls with enlargements might be unrecognized cases of congenital syphilis without other stigmas or positive serologic reactions. This does not seem to be remotely possible; even if it were, the bilateral distribution of the lesions would still demand explanation. 3. The enlargements may be of a different type from those described by Higouménakis, in which case the sign would obviously have little value as a stigma of congenital syphilis. On the other hand, if the lesion in their nineteen cases of congenital syphilis is identical with that described by Higouménakis, its distribution is certainly not unilateral, and since it can occur in normal controls it cannot be accepted as reliable evidence of congenital syphilis.

Brain Potential Changes Induced by Metrazol.—Rubin and Wall recorded the brain potentials of eleven schizophrenic patients given twenty-eight injections of metrazol. The records were started five minutes before the injection and continued up to one hour in some instances. Characteristic alterations of the electro-encephalogram were observed when metrazol evoked an emotional response or a seizure. When neither of these reactions occurred there were no changes in the electrical activity of any of the major regions of the cerebral cortex. The cortical response to metrazol may be divided into three types. 1. The alpha (ten per second) rhythm was slowed to about six per second, when only a mild emotional reaction, usually appearing as a momentary look of apprehension, was induced by metrazol. 2. As a rule the electrical activity of only the frontal lobes was appreciably altered during a severe emotional episode. The time for complete reestablishment of the premetrazol electro-encephalogram was directly proportional to the severity of the emotional response; the more severe the response, the longer the recovery time. 3. During a metrazol seizure large (250 microvolts) waves appear from six to twenty seconds after the injection of metrazol, marking the first myoclonic stage, and continue for from three to ten seconds. During the tonic stage, which occurs from fifteen to thirty seconds after injection and lasts for from ten to thirty seconds, the electro-encephalogram is characterized by high voltage spikes which have the frequency of muscle poten-

tials. The second clonic phase occurs from thirty to fifty seconds after the metrazol injection, lasts from twenty-five to forty seconds and is associated with cortical potentials at three to four per second and 1,000 microvolts in amplitude; they become slower, decrease in voltage, and appear with a spike component toward the end of the seizure. Immediately on cessation of the convulsions, at which time the patient may exhibit severe emotional symptoms, the amplitude of the potential changes dropped markedly and the pattern was one of even slower, but more irregular, activity for the next five to ten minutes. The final phase, lasting until the patient was fully recovered, consisted of an increase in frequency and a dropping out of the irregular, slow waves. This last phase exhibits two of the properties of the electro-encephalogram during sleep: (1) the predominant activity shifted back and forth from an almost completely recovered level to one resembling the stage immediately following the seizure, and (2) as early as ten to fifteen minutes before the patient opened his eyes and spoke spontaneously he would respond to requests by speech or by movement. The electro-encephalogram reverted to the premetrazol level while the patient was responding to the request. Immediately after this the "drowsy" potential pattern typical of this phase reappeared. These two changes correspond to the shifts in the level of the cortical activity during sleep which occur spontaneously and on arousing the attention of a sleeping subject.

Sulfapyridine in Urinary Infections.—Melton used sulfapyridine in the treatment of seventy-one cases of cystitis and pyelitis. Of nineteen cases of cystitis twelve were cured and of fifty-two cases of pyelitis forty-four were cured. There were fifteen failures. There were fifteen instances of pyelitis of pregnancy, in twelve of which cures were obtained. The patients with either condition responded readily to treatment and were cured after a period of three to seven days, except two whose treatment was prolonged for ten days. One patient with acute cystitis had retention of urine after acute poliomyelitis. Most of those with pyelitis of pregnancy were cured in a few days, and one of them with an unidentified non-lactose fermenting coliform organism responded to sulfapyridine after failing to do so to sulfanilamide. Of the patients with chronic pyelitis who were cured, one had renal calculi and had previously been unsuccessfully treated with sulfanilamide. Among those with chronic cystitis who were cured, two were suffering from diabetes mellitus and one had undergone prostatectomy. The commonest organism encountered in this series was *Bacterium coli*. Occasionally other organisms were found alone or together with *Bacterium coli*. Of these, *Bacillus pyocyaneus* and *Staphylococcus albus* responded well to treatment. On the other hand, *Streptococcus faecalis* was resistant to sulfapyridine in the same way as it is to sulfanilamide, though one case of pyelitis of pregnancy caused by this organism was cured. Infections with *Bacillus proteus* showed a varied response, for, although cures were obtained in several instances, some of the chronic cases did not clear up. In general, failure was encountered in chronic urinary infections with a focus of infection, such as a calculus or bladder diverticulum or with retention of urine—particularly when these conditions were associated with renal impairment and other debilitating states, such as old age and anemia. A further factor in failure was the presence of mixed bacterial infections. However, the presence of the foregoing complications does not necessarily prevent cure.

Serum Potassium and Calcium in Insulin Shock Therapy.—Clegg chose four male patients at random, all having been under treatment by hypoglycemic shocks for at least two months. At varying intervals blood examinations were made; the serum potassium and serum calcium were estimated before the morning injection of insulin and again just before the interruption of coma. Twenty observations on the serum potassium and seventeen on the serum calcium were made. Except on four occasions, the precoma level of the blood potassium was always above the normal, i. e. from 19 to 21 mg. per hundred cubic centimeters and often markedly so, and in no case was it below normal. The precoma level of the blood calcium was normal, i. e. from 10 to 11 mg. per hundred cubic centimeters in twelve of the seventeen estimations, and in the remaining five there was only a slight increase. It was found that the "resting" potassium fluctuates, but always above the normal level. During coma the potassium tends to fall below its precoma level. The "resting" calcium only occasionally deviates from the normal and then always above the normal level. During coma the calcium tends to remain at its precoma level. During coma the potassium calcium ratio tends to fall.

Abscess of the Lung.—Viswanathan presents a clinical study of thirty-two cases of abscess of the lung, that is a solitary collection of pus within destroyed lung parenchyma. The right lung was involved in seventeen and the left lung in fifteen cases. Lung abscess has been found to be more common between the ages of 20 and 40. There is always a preponderance of males in the proportion of three or four to each female. In the present series twenty-six were males and six females. All but two of the cases were primary or idiopathic, no history of operation or pneumonia was available in twenty-eight cases and two cases were secondary to bronchiectasis. Available literature shows that no single organism can be considered to be the causative factor in abscess of the lung. This was confirmed by cultural examinations and in most of which staphylococci, streptococci, pneumococci, Friedländer's pneumobacilli, fusiform bacilli and spirilla were found in different combinations. In only one case in the present series were pneumococci found in pure culture both in the sputum and in the pus removed directly from the abscess cavity during operation. Fusiform bacilli and spirilla were found in only seven cases. The pathogenesis of the idiopathic pulmonary suppuration is difficult to determine. The infecting organisms may be brought to the lung by either the blood or the lymph stream. In some cases the abscess may result from a mild or abortive pneumonia or from a form of pulmonitis recently described by Scadding (1937) as disseminated focal pneumonia. The disease started insidiously with malaise, irregular fever and slight cough in eight cases. In twenty cases the onset was sudden. In five cases it started with fever alone, lasting for more than two weeks before other symptoms such as pain, cough and expectoration occurred. Cough was the first symptom in three cases. Fever, pain and cough occurred more or less simultaneously in twenty cases. Purulent expectoration was present in twenty-six instances for from five days to five weeks after the onset of the disease. The sputum was foul smelling in twenty-two. Hemoptysis of varying degree was noticed in sixteen cases, but only once was the onset heralded

by severe spitting of blood and fever. Clubbing of the fingers developed in four. Pain over the chest is common in abscess of the lung irrespective of its anatomic location, the character of the pain being a dull ache over the chest, continuous and not related to respiratory excursions except when there is associated pleurisy. Physical signs vary with each case and depend on the area involved. Often they were so few as to lead to doubts and sometimes errors in diagnosis. Abscess of the lung generally appears in the roentgenogram as a circumscribed opacity of more or less uniform density. When there is air and pus inside the abscess cavity, a fluid level can be seen. Sometimes the shadow of the abscess is irregular at the margins owing to pneumonic consolidation in the neighboring lung tissue. Rapid changes in the size and shape of the shadow, as revealed by serial roentgenograms, suggest spreading gangrene of the lung. The prognosis is serious. Opening and draining the abscess externally was resorted to in ten cases with five deaths; pneumothorax was induced in four with one death. Eighteen patients were subjected to various medical treatments; five recovered completely, three absconded, three preferred to discharge themselves against medical advice and the remaining seven died. Generally, it is advisable to try conservative measures in acute cases such as rest and postural treatment. Various drugs have been tried. The sulfonamide group of drugs, particularly injections of benzylsulfanilamide, was tried in four cases. In the first patient so treated the temperature was normal within four days. Unfortunately he refused to remain in the hospital for the completion of the treatment, but inquiries made after three months elicited the information that he was alive and healthy. In the second case there was decided improvement both clinically and roentgenologically, but an abscess developed in the brain (confirmed at necropsy) one month later. The remaining two patients were completely cured within from one to three months after the sulfonamides were started. If after six weeks of medical treatment the patient does not recover the abscess should be fully tried in a small percentage of cases in which the abscess is away from the periphery of the lung and is freely communicating with the bronchus.

Sweet Potatoes and Nutrition.—Adolph and Liu report the results in which sweet potatoes furnished practically the sole item of diet for from five to eight weeks for three human subjects. Nitrogen balances and metabolism rates were measured every four days. The white sweet potato of North China was used. Each subject determined at the beginning of the experiment the amount of sweet potato which could be comfortably eaten: this amount (on the uncooked basis) varied from 1.7 to 3.4 Kg. (1,700 to 3,400 Gm.) a day. The subjects ate three meals a day and the daily intake was maintained practically constant for each subject throughout the experiment. The sweet potatoes after removal of the skin were weighed and lightly fried in pork fat. The manner of cooking was not varied from day to day. In addition to the sweet potatoes, one subject received one pear daily and two subjects were given one bowl of cabbage soup a day. The nitrogen balance was maintained when the subject's daily intake of sweet potato approximated 2 (2,000 Gm.) or more kilograms. While the subjects continued in good health, on several occasions during the experiment they reported that they tired quickly when engaged in strenuous effort. This corresponds in general to the verdict of the North China farmer who asserts that sweet potatoes are inferior to millet as a strength-producing food.

Treatment of Vesical Cancer by Radium.—Darget and Lange review the results they obtained with radium treatment in sixty cases of cancers of the bladder. In eight of these cases a microscopic examination could not be made, but the malignant character was clinically evident. However, the authors subtract these eight cases and consider only the fifty-two cases in which the malignant character of the tumor had been histologically verified. These fifty-two patients had all been treated by the same method, namely by the implantation of radium needles into the opened bladder in a single session. Two types of malignant tumors can be differentiated: (1) the sessile tumors, namely those without pedicle in the restricted meaning but movable on the underlying musculature; (2) the infiltrated tumors. In the latter type three subgroups are differentiated: (a) those with beginning infiltration, the base of which is adherent and has lost its mobility, (b) those the base of which is manifestly infiltrated, (c) those which have ulcerated the vesical wall, the trebrating tumors, which were infiltrating from the beginning. After listing in a table the sixty cases of vesical cancers which were treated with their method of radium therapy, the authors reproduce several photomicrographs and show diagrams illustrating the introduction of the radium needles. Analyzing the results obtained in sixty cases, they say that the immediate operative mortality amounted to 3.3 per cent; that is, two of the sixty patients died in immediate connection with the operation. During the first two months following the operation, four of the patients died of azotemia and two died as the result of metastases. Estimating the late results obtained in the fifty-two cases that had been histologically verified the authors say that, of twenty-five cases that date back more than five years, survival to the present resulted in nine (36 per cent) and ten were cured (40 per cent); of the forty-five cases that date back more than eighteen months, survival to the present occurred in twenty-two; twenty-eight cures lasted more than two and one half years. Of thirty-three cases with infiltrating tumors, survival to the present occurred in nineteen; of the thirteen which date back more than five years, survival to the present occurred in five. Of the nineteen patients with sessile tumors, nine are still living; of the twelve that date back more than five years, four are alive but seven were cured, three having died of intercurrent diseases, while the local cure still persisted. To emphasize the efficacy of their form of radium therapy the authors point out that of fifteen patients with extremely grave forms of vesical cancer eight are still alive. They emphasize the necessity of careful surgical preparation, an exact technic, strict postoperative care and cystoscopic controls at regular intervals. They continue to advocate this treatment.

- *Cranial Hypertension in Relation to Arterial Hypertension. Riser, J. Planques and Paulette Barbier.—p. 649.
- Bone Conduction. M. Aubry and J.-C. Giraud.—p. 653.

Cranial Hypertension and Arterial Hypertension.—Riser and his associates present a study of the interrelations of cranial and arterial hypertension. Their observations are based on 140 patients, who were given 5,000 manometric measurements in strictly horizontal lateral decubitus. They find 20 cm. of water the maximal craniospinal pressure (with the average ranging between 15 and 18 cm.) for patients in recumbency and 48 cm. maximal for patients in the sitting position. The authors distinguish between uncomplicated and complicated arterial hypertension in relation to cranial hypertension. The former does not induce cranial hypertension, as the case history

of seventy-five of their patients reveals. On the other hand, complicated arterial hypertension often induces cranial hypertension in various phases. Of fifty patients, 34 per cent clearly showed cranial hypertension; twenty patients showed moderate cranial hypertension (from 23 to 30 cm.); ten from 30 to 35 cm., and four respectively 40, 48, 50 and 52 cm. Tests were made in the horizontal position. In three instances decubitus tests invalidated the normal readings indicated by tests made in the sitting position. The authors stress the importance of systematic examinations of the fundus oculi. Papillary edemas were particularly frequent in complicated arterial hypertension. In twenty-three of twenty-five patients, marked venous tension fluctuating between 15 and 40 cm. accompanied cranial hypertension. Toxic factors such as faulty metabolism of proteins, chlorides and water were also clearly causative of cranial hypertension. However, seven patients with pure azotemic nephritis and a urea content of from 2 to 3 Gm. remained unaffected by cranial hypertension. Seven patients with high cation, with blood lavage in two cases, showed disintoxication; abnormal chloremia and azotemia and cranial hypertension disappeared. Likewise a local intracranial lesion, such as cerebromeningeal edema, increased cranial hypertension in complicated arterial hypertension. Arterial hypertension in also be of central neurologic origin, secondary to a lesion or a functional disorder and so, of necessity, accompanied by cranial hypertension. Some of the practical consequences and symptomatic values deduced by the authors from their observations are noted. Uncomplicated arterial hypertension is never accompanied by cranial hypertension even if it has been high for a long time. They suggest that the tests be applied to determine the primary or secondary nature of cranial hypertension when this is clinically, ophthalmologically and manometrically established beyond doubt. Tests to determine between the presence of a cerebral tumor and a "pseudotumoral arterial hypertension" are neither difficult nor require a long time. In forty of fifty cases of arterial hypertension with pronounced cranial hypertension, diagnostic tests were directly determinative. Arterial and cranial hypertension unaccompanied by certain indications such as cardiovascular-renal disturbances, ophthalmologic signs and toxicity require especially careful tests—indicated by the authors—to determine the neurologic origin of the condition, to be supplemented, if necessary, by ventriculography. Sometimes ventriculography would show the absence of a tumor and the subsequent evolution would point to a serious and complicated arterial hypertension. Such cases are not numerous but need to be noted, as they reveal that all the factors of cranial hypertension coexistent with arterial hypertension are not known. In two instances the ophthalmologic and manometric indications of cranial hypertension preceded all the others by several years. The authors summarize their important observations in three groups: (1) coexistence of crano-intracranial lesion and arterial hypertension without a close causal interrelationship, (2) central neurologic lesions inducing and controlling arterial hypertension and (3) arterial hypertension controlling cranial hypertension (the largest group).

Habitual Dislocation of Knee Cap.—Godoy Moreira designates as habitual dislocations those which recur readily either in the course of ordinary movements or as the result of slight traumas that are readily tolerated by a normal articulation. Persons who are subject to habitual dislocation of the knee cap frequently take serious falls, sustain fractures and

are likely to have serious street accidents. The disorder seems to be considerably more frequent in women than in men. That heredity plays a part in the etiology is indicated by the fact that familial occurrence has been reported a number of times. The dislocation is always outward. This fact finds its explanation in the morphologic alterations that are seen most frequently: capsuloligamentous aplasia, aplasia of the external condyle, internal rotation of the femur and external rotation of the leg, genu valgum with outward displacement of the patellar tendon. The most important anatomopathologic aspects of habitual rotular dislocation are (1) laxity and thinning of the articular capsule, sometimes tearing away of the internal lateral ligament and of the internal capsuloligamentous covering, (2) atrophy of the tendon of the quadriceps, the patella and the patellar tendon, which is displaced outward. Absence of the meniscuses and of the cruciate ligaments has also been observed. During the dislocation the pain may be slight or considerable. In the old and frequent dislocations the pain is nearly always slight, functional inadequacy being the chief symptom in these cases. In general, the patient complains that he becomes easily fatigued; he lacks confidence in his leg and it is difficult or even impossible for him to ascend and descend stairs. Roentgenograms that are taken during the dislocation show the patella from the side and lateralized, if the exposure is taken in the anteroposterior direction of the knee. During the interval, roentgenography explains certain details, for instance the existence of a more or less pronounced valgum. Another interesting point is the elevation of the patella, which the author had occasion to verify in two of the three reported cases. Regarding the prognosis he says that if treatment is neglected a serious infirmity may develop which may greatly impair the working capacity. Treatment is possible by means of a supporting apparatus, for instance that of Handeck, or by surgery. The treatment with the apparatus does not prefer a surgical solution and the patients themselves usually numerous operations that have been recommended and suggests that it is advisable to choose that method which is best suited for the individual case. The selection should be based on a careful study of the pathogenic mechanism and of the anatomic changes. The author thinks that the following operations will be most frequently indicated: that of Roux, a modification of that of Krogins, that of Albert Mouchet and that of Albee.

- Test of Sedimentation Speed of Erythrocytes in Normal Guinea Pigs. P. Nicolle and H. Simons.—p. 401.

Bone Marrow in Mycosis Fungoides.—Lapière and de Weerd state that the modifications of the structure of the bone marrow which occur in mycosis fungoides have been studied with the aid of sternal puncture only in a comparatively small number of cases. They review studies made by Santoian, by Cottini and by Tzanck and his associates and then describe their own observations on eleven patients. In eight of them a cutaneous biopsy showed the existence of a malignant fungoid granuloma. Three clinical forms of the disease can be differentiated in the cases discussed here: the form of Hallopeau and finally the form with tumors at the onset. Four of the eleven patients had reached the last period in the evolution of the mycosis, for they died several weeks after the examination of the bone marrow. In this report the authors summarize the hematologic observations and compare the results with those obtained in ten normal subjects. They found that it is the reticulo-endothelial reaction which constitutes the most typical medullary modification in the course of mycosis fungoides. This reaction varies greatly in intensity. In order to estimate it the authors compared the percentages found for the reticulo-endothelial cells, the monoblasts, the

lymphocytes and the histoid plasmocytes. Although together these elements amount to about 4.15 per cent in the normal state, in five of the cases they amounted to from 5 to 10 per cent and in four they amounted to more than 10 per cent with a maximum of 20 per cent. Only one of the cases observed by the authors attained values reported by Tzanck; thus such values must be regarded as exceptional. The histoid reaction was not constant. It was lacking in one of the cases of mycosis fungoides with tumors at the onset. The reticular cells were not always increased. They exceeded the normal values in only six of the cases. The medullary plasmocytes, which, with rare exceptions, are of histoid origin, exceeded the normal values in seven of the cases. But the histoid lymphocytes account for the greatest part of the observed changes. The authors were unable to find in the marrow of patients with mycosis fungoides cells that are characteristic for this disorder; the nuclear polymorphism cited by Tzanck is a weak differential characteristic. In the concluding summary they point out that the bone marrow of patients with mycosis fungoides may present the following modifications: (1) a polymorph histoid reaction, which is rarely missing but which remains rather discrete except in the advanced cases; (2) an inconstant eosinophilia, either existing alone or combined with eosinophilia of the blood. In advanced cases of the disease there may be added (3) an inhibition of the transformation of the metamyelocytes into neutrophil leukocytes and (4) disturbances in the maturation of the erythroblasts.

Third Generation Syphilis.—Merlin thinks that not only the rarity but also the practical significance of observations on the transmission of congenital syphilis by the second generation justify the report of cases of this type. After describing the signs of congenital syphilis in a child who was born in 1938, he reports the observations on the mother, who had a strongly positive Wassermann reaction. The child's father was free from syphilis, as were also his parents. The mother of the woman, that is the grandmother of the child, had positive serologic reactions for syphilis, and the possibility of a venereal infection by her husband, who for ten years had had dementia paralytica, was admitted. The author points out that, according to Fournier, Finger and others, the following points must be fulfilled in order to establish the transmission of congenital syphilis to the second generation: 1. There must be definite proof of the existence of syphilis in the grandmother. 2. It must be proved that the mother did not acquire syphilis but that she has congenital syphilis. 3. There must be proof of congenital syphilis in the child. The author shows that in the reported case these requirements were fulfilled.

Pluriphase Tuberculosis of Refractory Organs (Pancreas, Stomach and Esophagus) with Aspects Similar to Those of Lymphogranulomatosis. V. Chiodi.—p. 266.

Lipases in Blood Serum in Pulmonary Tuberculosis.—Tosi determined the lipases in the blood serum of thirteen normal persons and of forty-five patients who were suffering from pulmonary tuberculosis of either the exudative or the productive type. He found that the lipolytic index of the blood serum (including blood lipases and lipases which are resistant to atoxyl and to quinine) is normal in the benign form of exudative or productive tuberculosis and is diminished in grave forms of the disease. In the course of the disease the lipolytic index of the blood serum increases with the local and general improvement of the patients, either from an organic reaction to proper medical treatment or from satis-

factory results of collapse treatments, and also in the course of transient pleural complications. It diminishes from propagation of tuberculosis, development of new parenchymal lesions and when there are progressive loss of weight, lowering of the general health condition and toxemia. The total lipases of the blood serum and the lipases which are resistant to atoxyl and to quinine follow a parallel behavior in relation to the evolution of pulmonary tuberculosis. The fact shows probable common origin for these types of lipases, which had been considered as having originated in different organic structures. It shows also that the enzymatic action of these types of lipases is identical.

*Chancre of Tonsils. F. Cora Eliseht and A. Agüero.—p. 221.

Early Chancre of Tonsils.—Cora Eliseht and Agüero state that chancre on the tonsils is rare. An early diagnosis is of importance because the chancre may show an atypical aspect (owing to the presence of complicating buccopharyngeal infections) and the local lesions are similar to those of Vincent's angina or else to peritonsillar phlegmon. The main clinical characters of early tonsillar chancre are as follows: The lesion is generally unilateral but it may be bilateral. The involved tonsil protrudes in front of the other one with an aspect similar to that of phlegmonous tonsillitis. On palpation it gives the sensation of being a woody structure. Local pain is moderate. The infiltration diffuses from the tonsil to the larynx, uvula and nearby structures. There is adenitis back of the maxillary angle and in the carotid region. Sometimes there is also hypertrophy of the local lymph nodes. The clinical diagnosis is verified sometimes by the appearance of secondary lesions and in all cases by the positive results of serologic tests for syphilis and by the satisfactory results of antisyphilitic treatment. The authors report three cases in women.

*Demonstration of Allergic Factors in Pathogenesis of Eclampsia. E. Jungmans.—p. 656.
Mutual Intra-Uterine Impairment of Twins. H. Ruhl.—p. 702.

Allergic Factors in Pathogenesis of Eclampsia.—Jungmans reviews the literature on the tissue changes in allergic conditions and on the allergic theories of eclampsia and shows that, although many clinicians and pathologists have included eclampsia in the group of allergic conditions, the experimental proof for the allergic character of eclampsia is still to be furnished. It was the author's aim to produce in the liver and kidneys of animals, by means of the serum hyperergy experiment, the tissular changes that are found in these organs in women with eclampsia. On the basis of his experimental studies on animals, he considers it justified to regard the pathologic anatomic aspects of eclampsia also from the point of view of an allergic-hyperergic process and thus interpret the specific organic changes as the manifestation of a tissular hypersensitivity against a still unknown protein product (antigen) which during pregnancy is introduced into the maternal organism by way of the uterine vessels and sensitizes it. To be sure, the author is aware of the fact that this explanation does not solve the problem of eclampsia in its entirety and that it cannot clarify the different clinical symptoms of eclampsia, for instance the convulsions. He thinks that still other factors are of fundamental significance in the pathogenesis of this disorder. The experiments carried out by the author indicate that the serum of eclampsia as well

as the fetal serum must contain a substance that has the action of an antigen. Using these two types of serum in the allergy experiment, he was able to produce especially in pregnant rabbits the hepatic and renal changes that are characteristic for eclampsia, whereas it proved impossible to produce these changes with the serum of healthy pregnant women and with animal serum. In this connection the author cites observations which he made in the course of intracutaneous tests on women with the nephropathy of pregnancy. He observed that during the last months of pregnancy they gave positive reactions in response to intracutaneous vaccination with fetal extract. He thinks that with the necessary reservations this might be regarded as indicative of allergic hyperergic processes in the development of eclampsia.

Pulmonary Cancer and Lung Abscess.—The increase in the incidence of pulmonary cancer created, according to Peters, new diagnostic problems, among which the differentiation of the cancer from a pulmonary abscess is particularly difficult. The author points out some of the difficulties in a discussion of seven cases observed in Sauerbruch's clinic. The recognition of the cancer in its infiltrating stage is now readily accomplished with the aid of tomography. The diagnosis is made much more difficult when the tumor breaks down and forms a cavity. The following symptoms are suggestive of a tumor rather than of an abscess: marked dilatation of the thoracic veins; local edema of the arm, face or a limited area of the skin of the thorax; displacement of heart tones; spontaneous paralysis of the recurrent or the phrenic nerve, rapid refilling of a pleuritic effusion after tapping, and, in particular, stenosis of a bronchus followed by atelectasis. The latter is made recognizable by the narrowing of the intercostal spaces and with the aid of tomography. The differentiation in many cases may be made with the aid of bronchoscopy. The value of tomography, however, is even greater. Exploratory thoracotomy is indicated in cases in which the diagnostic methods mentioned fail to make the differential diagnosis, especially if the patient expectorates large amounts.

Acute Pancreatitis.—According to Griessmann, fifty cases of acute hemorrhagic pancreatitis and thirty cases of acute edema of the pancreas were treated at the Giessen clinic between 1931 and 1937. During a twenty-two year period (1909-1930) Bernhard reported from the same clinic sixty-three cases of acute hemorrhagic pancreatitis and nine cases of acute edema of the pancreas. The author believes that the increase in the cases of acute pancreatic disease from three per annum to seven was due to improved nourishment, since most of his cases were associated with obesity. The author stresses the fact that improvement in the diagnostic methods enables one to make a diagnosis in practically all cases. He further stresses a change in the attitude toward early operative treatment in the cases of acute pancreatic necrosis. Whereas Schmieden in reviewing 1,500 cases of acute pancreatic disease in 1927 urged immediate operation for every case of acute pancreatic disease, Walzel, Nordmann and others pointed out subsequently that this procedure did not reduce the mortality and perhaps even increased it. In the author's sixty-eight

cases of acute pancreatic disease in which operation was performed during the quiescent stage, the association with gallstone disease was demonstrated in sixty-four (94.2 per cent). In three fourths of these cases there were small stones, which fact suggests that the gallstone disease was not of long standing. Stones in the common duct were observed in 6.5 per cent of his cases. In the author's series there were 90 per cent women and 10 per cent men. Association between pancreatic disease and a disease of the biliary passages was established in 94.2 per cent of the cases. Daily determination of diastase in the urine proved to be a valuable diagnostic method. A single determination is not reliable. In 20 per cent of the cases there was no increase in the diastase. Determination of fasting blood sugar is of considerable importance in the diagnosis of acute pancreatic disease. The function of the island apparatus of the pancreas is best determined by the dextrose tolerance test. Among other diagnostic methods the author includes the determination of lipase in the blood serum, the leukocyte count, the estimation of urobilin and urobilinogen in the urine, and determination of residual nitrogen in the serum and of albumin in the urine. The employment of all these diagnostic methods makes it possible to arrive at a correct diagnosis in the majority of the cases. The clinic at Giessen has adopted since 1931 a conservative attitude in the treatment of these cases. In this treatment no nourishment of any kind is given, fluids are administered by rectum and circulatory weakness is treated by a 5 per cent dextrose intravenous drip. Atropine is given intravenously to allay the irritability of the vagus nerve and morphine is administered in high doses to control the pain. To prevent recurrences, patients are submitted at a later stage to operative intervention the aim of which is to remove the gallstone disease. The decision in each individual case as to when to operate is determined by the state of the circulation. The average lapse between the onset of the disease and the operation in the author's series was eleven days. The author points out that the mortality rate for Schmieden's series was 51 per cent and for Bernhard's 34 per cent, while in his series it amounted to 13 per cent.

Estrogenic Hormone and Nervous Factors.—Herold and Effkemann point out that clinical observations indicate that sympathetic centers and tracts are involved in incretory functions. Conditions like psychogenic amenorrhea, hysterical pregnancy and the development of amenorrhea following the use of narcotics with a central point of attack or following diseases of the diencephalic system induced the authors to investigate the part played by the sympathetic nervous system in the incretory functions of the anterior lobe of the hypophysis. Although there was no longer any doubt that the hypophysis and the diencephalon form a functional unit, there was as yet no definite proof for the involvement of sympathetic centers and tracts in the incretory functions of the anterior lobe of the hypophysis. In recent experiments on rats the authors were able to demonstrate that the administration of estrogen fails to produce indirect reactive luteinization of the ovaries if the treatment is preceded by division of the hypophysial infundibulum; that is, the diencephalon and the hypophysial infundibulum are the nervous tracts that are necessary for the incretory hypophysial function. This observation made it seem likely that the action of the estrogenic hormone on other organs, such as the mammary gland, is subject to the same mechanism and so the authors subjected male and castrated female rats in which the hypophysial infundibulum

had been cut to prolonged administration of estrogen. It was found that the structural changes in the mammary gland, the cystic fibrosis, which is produced by the estrogenic hormone in male animals in the presence of an intact infundibulum, did not develop following division of the infundibulum. This proves that the action of the estrogenic hormone on the mammary structure is not a direct one but takes place by way of the hypophysis and that the hypophysis and the diencephalic system form a functional unit. An incretory stimulus, as it is produced by the estrogenic hormone, influences the diencephalon by humoral means, and from there it is led by nervous channels to the anterior lobe of the hypophysis, where, after its effect has been redirected and the incretory function changed, it determines the morphologic behavior of the mammary gland. Thus it is demonstrated that sympathetic tracts and centers are necessary for the development of physiologic and pathologic growth processes in the mammary gland.

Interrelations Between Ovaries and Thyroid Under Influence of Vitamin E.—Schneider points out that castration is followed by a reduction in the activity of the thyroid, whereas the administration of estrogen counteracts this reduction. This indicates that the estrogenic hormones not only act on the genital apparatus but also intervene in the general hormonal regulation and exert an influence on the activity of the thyroid. The author further reviews the effect of various types of avitaminoses (A, B, C and D) on the condition of the thyroid and then states that E avitaminosis acts on the thyroid in a similar manner to castration. Moreover, E avitaminosis impairs the ovarian function but apparently does not entirely abolish it. As the chief sources of vitamin E in human foods the author mentions lettuce, vegetable oils, pork fat and butter. In studies on the interrelation between the action of vitamin E, the ovarian hormones and the thyroid he found that, if vitamin E in the form of wheat germ oil is administered simultaneously with estrogen, much smaller quantities of estrogen are effective than is the case otherwise. Thus vitamin E increases the efficacy of estrogen.

*Attempt at Crystallographic Diagnosis of Carcinoma. S. Rascher and J. Trumpp.—p. 544.

Crystallographic Diagnosis of Carcinoma.—Rascher and Trumpp assert that, if a solution of copper chloride is put on a glass plate that is free from defects and if the solution is dried within fourteen to eighteen hours, the plate shows a bluish green, more or less dense (depending on the concentration, from 5 to 20 per cent), unevenly distributed crystalline deposit, which is mixed with amorphous and crusted masses. If, however, diluted organic substance, such as blood in distilled water, is added to this deposit, the plates show well shaped crystalline needles. Why living substances act in this manner on the process of crystallization has not been explained as yet, but the fact remains. Even more surprising, but also quite evident, is the fact that the addition of blood from healthy subjects produces an entirely different picture of crystallization than does the addition of blood from patients. Whereas in healthy persons crystallization proceeds in a ray pattern from one point that usually has a slightly eccentric localization, in diseased persons the crystallization presents a

decentralized, disorganized picture. The unicentral direction of the crystalline needles is lacking and there are other, independent, centers of crystallization, the radiating bundles of which either are strictly separated from the adjoining ones or partly cover them. The authors say that these observations were made first by Pfeiffer and were corroborated by their own experiments. Pfeiffer maintained also that there are characteristic pictures of crystallization in certain diseases, for instance that a certain cross form characterizes tuberculosis and a wing form carcinoma. After the authors had determined that the picture of crystallization can be influenced by certain protein constituents, they decided to give their attention to the crystallographic aspects of the blood of patients with carcinoma. They examined 246 specimens of human blood. In ninety-eight of these the plates showed no signs of carcinoma and the clinical diagnosis of these cases tallied with the outcome of the crystallographic test. In 148 cases the plates indicated the presence of carcinoma, but in eleven of these this diagnosis proved incorrect, for three of them were definitely free from carcinoma and in eight other cases sarcoma and not carcinoma existed. In nine other cases the clinical diagnosis of carcinoma was still doubtful, but in the other 128 cases the crystallographic diagnosis of carcinoma tallied with the clinical diagnosis. Tests were made also on sixty specimens of animal blood. The crystallographic test gave erroneous results in three of forty animals with carcinoma and in two of twenty animals without carcinoma. The authors think that the cited figures are proof that this method deserves attention. It has the disadvantage that it requires an extremely exact technic and that only fresh blood (at the latest after five hours) can be used.

Psychopathology and Exophthalmic Goiter.—Grewel says that serious psychoses of various types may occur in exophthalmic goiter and that even in the absence of typical psychoses certain nervous symptoms generally characterize patients with exophthalmic goiter. Among the latter there is restlessness, with a continuous drive to hurry and with nervous haste in all activities. Even more characteristic is the so-called tension of expectancy regarding everything that has to be done. All psychic processes, including the emotions, are more or less impetuous. The emotions are accompanied by and interwoven with strong physical sensations. The author concludes that the rapidity and impetuous intensity which characterizes the psychopathology of the patients with exophthalmic goiter is the manifestation of the increased metabolism.

Winckel's Disease with Recovery: Case. P. H. Fiedeldy Dop.—p. 397.

Prontosil Rubrum in Treatment of Scarlet Fever.—Ström mentions several investigators who tried sulfanilamide preparations in scarlet fever and then reports his own observations. He began the treatment with prontosil rubrum in the early part of 1937 and continued it until the early part of 1938. The substance was used only in cases of pharyngogenic scarlatina, not in surgical or puerperal scarlatina, and only in

those cases which were uncomplicated at the time of hospitalization. The prontosil rubrum was administered to every second patient with scarlatina who entered the hospital, the other patients serving as controls. In patients in whom the fever was extremely high and in whom the general condition was greatly impaired serum or of convalescent serum. Pron-tosil rubrum was given also to every second one of the patients receiving serum therapy. Thus there were four groups of patients: a prontosil group and a control group, a serum-groups comprised 100 cases each, the last two twenty-two cases each. Thus 122 patients received prontosil and 122 did not. Adults and children over 10 years of age were given three times daily one tablet, children between 3 and 10 years of age were given three times daily one-half tablet and children less than 3 years of age were given three times daily one-fourth tablet. Summarizing the effects produced by the prontosil, the author says that the fever period was shorter in the patients treated with prontosil. Of the patients who remained free from complications during their entire stay at the hospital, the prontosil group showed a more rapid return to normal sedimentation values than did the group not treated with prontosil. The incidence of complications was reduced by one third in the patients who had been treated with prontosil. Those complications which are the result of general toxic effects were not reduced in the patients receiving prontosil, but only the local inflammatory complications of the pharyngeal infection. The relapses (one among the prontosil group and eight among the others) as well as the late complications, in which new exogenic infections probably play a part, were less frequent among the patients who received prontosil therapy. The length of hospitalization was shorter with prontosil treatment than without it. Thus it may be said that treatment with prontosil shortened the duration of primary scarlet fever, reduced the frequency of complications and probably also conferred some protection against new exogenic infections. Secondary toxic effects of prontosil were slight in this material, probably because comparatively small doses were given.

- Colloid Stones. H. Krieger Lassen.—p. 909.

Hemopoiesis in Pernicious Anemia.—Bang maintains that pernicious anemia originates because a principle necessary for the formation of red blood corpuscles or for certain preliminary stages is lacking and the ability of the organism to form blood cells with normal span of life is reduced, causing a degeneration both in the bone marrow and in the peripheral blood. In the marrow there is hyperplasia together with hyperactivity. The "pernicious" organism may recur to an "embryonal" regeneration type, which may help more or less for a time. Megaloblastosis is regarded as the sign of maximal activity. On specific treatment the marrow is supplied with the lacking principle, cells with normal viability are formed and in the main a regeneration sets in like that which would occur in the "not pernicious" organism if it were to meet the deficit in the blood corpuscles. The interval between the start of treatment and the first signs of increase in the peripheral blood represents the time needed for replacing defective cells with normal cells. The permeability of the red blood corpuscles to certain substances, especially dextrose, is increased in untreated pernicious anemia. The permeability changes in marked degree immediately after the start of treatment and may become normal before the rise in blood values begins.

Resorption of Antipneumococcus Serum.—After injection of horse and rabbit antipneumococcus serum in rabbits by intravenous, intraperitoneal or intramuscular routes, Bjørneboe

and Clausen followed the concentration of antibodies in the blood by titration of agglutinins. The maximal concentration of antibodies in the blood was reached at once by intravenous injection, after from three to four hours by intraperitoneal injection and after from twenty-four to forty-eight hours by intramuscular injection. Similar conditions of resorption were found in a child aged 4 months in whom in unspecific protein therapy type IV rabbit antipneumococcus serum was injected intravenously, type VI intraperitoneally and type V intramuscularly, one directly after the other. The authors state that, if intravenous injection of antipneumococcus serum is difficult or impossible, intraperitoneal injection may be employed. If the serum is given intramuscularly, the dose must be considerably increased.

- Practical Supports for Patients in Operations on Kidney. A. Brekke.—p. 870.

Vertebral Hemangiomas.—Scheel says that vertebral hemangiomas, frequently found on anatomic examination, rarely give clinical symptoms. Only thirty-six cases with neurologic symptoms due to vertebral hemangiomas have been reported in the literature, and he adds two personal cases. Compression of the medulla, established in thirty-one cases, was most often caused by hemangioma masses in the epidural space which had broken through the vertebral body or arch. In seven cases the only symptom was pain in the back, in part radiating to the abdomen and lower extremities. The symptoms of compression or pain appeared in both old and young. The youngest patient was 15, the most marked symptoms were felt by patients about 20, and pain as the only symptom was observed in older patients. The neurologic symptoms as a rule begin with weakness in the lower extremities; paresthesia and pain generally follow and walking becomes difficult. A spastic paralysis may develop into a complete paralysis. Often paralysis of the bladder occurs early in the course. Occasionally the condition remains stationary. Usually there is progression in the course of months or years. The outcome is often fatal. In life the diagnosis of vertebral hemangiomas can be made only roentgenologically; shows a characteristic coarse-meshed structure. A vertebral hemangioma with neurologic symptoms calls for surgical or radiologic treatment. Operative treatment consists of laminectomy of the affected vertebrae and eventually also removal of the hemangiomatous tissue, which often extends epidurally. Improvement follows in from a few weeks to months. Fifteen patients with vertebral hemangiomas with symptoms of compression were operated on, with recovery or improvement in eight, no change in two and death from hemorrhage from the hemangiomatous tissue in five. Eight patients were given roentgen treatment, with marked improvement in seven and no change in one. Two patients were treated with radium, with marked improvement. According to Lièvre, roentgen treatment should be reserved for the milder cases with pain as the only symptom, operative treatment being indicated when there is paralysis of greater degree, in spite of the danger of hemorrhage. The author, however, says that some degree of compression of the medulla was present in four of the cases treated especially a powerful radium treatment might well be tried in cases of graver compression, if life is not in immediate danger. His two patients, women aged 73 and 56 with symptoms of pain, had favorable results from radium and roentgen treatment respectively. The cases from the literature are tabulated in detail.

EXPANSION OF FUNCTIONS AND RESPONSIBILITIES OF HEALTH DEPARTMENTS

CHAIRMAN'S ADDRESS

I. C. RIGGIN, M.D., D.Sc.
RICHMOND, VA.

The present changing sociological and economic conditions unquestionably develop a greater need than ever before for consideration of public health services which may or should be rendered in any community or locality. The functions and responsibilities of public health agencies are primarily the prevention of disease, the control of spread of disease and the conservation and preservation of the health of the people as a whole—national, state and local. In the United States, public health organizations have been developed to include federal, state and local or community health services. The federal health service has been organized and developed in such a manner that its functions in no way interfere with state and local health services. It has been charged with the performance of specified governmental functions. It acts as a coordinating body and makes available information nationally for the protection of the health of the people, and renders assistance to the state and local health agencies. Without doubt, because of the divided responsibility for the public health among several departments of the federal government, confusion at times has resulted. There should be a coordination of activities. Efforts have been made and should continue to be made to keep public health within the bounds of recognized governmental functions.

While public health is preventive, and the practice of medicine by the general practitioner as well as by many of the specialists is of necessity both preventive and curative, there is no reason why the practice of private medicine and public health should not go forward without divergence of thought and opinion and, through proper coordination of efforts, develop and render more and better service to all concerned. There are many phases of public health activity which are suitable for cooperative efforts between the physicians and public health agencies. However, there are certain underlying principles that should govern and always be observed. It should always be borne in mind that very few communities are alike, and many factors must be taken into consideration in planning and developing and carrying out any service to be rendered. If the practicing physician is familiar with the procedures to be instituted for the protection of the health of the

people, misunderstandings will be eliminated. Not only does the practicing physician have an integral part in preventive medicine, which is of course a means of safeguarding the health of the people, but he is the main factor in accomplishing results. The physicians should not only assist but take the leading part in determining any method for instituting, preventing and controlling disease, and all those engaged in preventive medical work should endeavor to increase the community's confidence in the medical profession.

To the practicing physician rendering service to the individual, it should be the aim of health departments to make every facility available that affects the spread of disease. By law the responsibility for the prevention of spread of disease is an obligation placed on health departments. It is required that every available means be instituted to discharge this responsibility. It is recognized that supervision of water supplies and sewage disposal, information pertaining to vital statistics, collection of reports on communicable diseases, and the institution of methods against the spread of disease are functions that can be performed only by a governmental agency. Other activities directly for the benefit of the practicing physician are diagnostic service, epidemicologic investigations and laboratory examinations. Public health laboratory examinations are not made simply as diagnostic measures but are made in order to aid in the control of disease in the community.

To draw a distinct line of demarcation between preventive medicine and curative medicine is an impossibility. Where one stops and the other begins cannot be definitely defined when consideration is given to the question of the prolongation and conservation of life in contradistinction to the prevention of a particular disease. Medical conferences and clinics which are conducted by health departments should be used as a means of education and to bring to the attention of the public the value and need of medical and public health services. It has been through the demand of the citizens and physicians that tuberculosis diagnostic clinics and sanatoriums have been established and thus become recognized definitely as a public health function. These clinics are a means to discover new cases of tuberculosis and to prevent and control the spread of this disease by having such discovered cases brought under the care of the family physician for advice, treatment and care, or to be institutionalized in a sanatorium, which is usually operated by a state health department or other governmental agency.

Maternity centers have been established in many sections throughout the country, and not only have there been developments in this field which have been educational in character but, in many instances, definite medical service has been rendered to expectant mothers and infants when they were unable for various reasons to

obtain medical service through other sources. This has unquestionably been a factor in reducing maternal and infant mortality rates. From an economic standpoint health supervision of the child has been demanded of health departments. This activity is not carried on alone by the official agencies but there is active participation by the medical profession.

Increased knowledge of the public relative to medical facts, and information available as to the possibilities of prevention as well as curative measures, indicate quite clearly that the physician must become more and more the adviser to his patients on preventive and hygienic measures.

Changes in economic conditions in the country during the past several years have presented new and perplexing problems to the medical profession. It can be stated without misstatement of facts that additional burdens have been placed on the medical profession in the care of the indigent sick. The care of the indigent sick may not be a function of the government, but it is a responsibility whether it be national, state or local. This service usually has been available only through the efforts of the practicing physician, who through his self sacrifice and humanitarian service cared for those unfortunates to his own detriment and loss.

With the passage of the Social Security Act there immediately followed additional responsibility of health departments; there was an expansion of public health services both in state and in local communities, and without doubt practically every feature of the Social Security Act has either directly or indirectly some relation to the public health. A greater feeling of economic security to be experienced by the wage earner and the persons looking forward to old age should contribute in some measure to better mental health; and relief from want and deprivation in childhood certainly should lessen, to some extent at least, the hazards of disease resulting from faulty nutrition and lack of medical care.

In the field of industrial hygiene it has been known for some time by the industrial hygienists that additional efforts should be directed toward the control and prevention of certain diseases which take a greater toll among those employed in industry than in other fields of endeavor. It might be mentioned that the death rate from pneumonia among this class of workers is far above that of the general population and that the death rate from tuberculosis is much greater among the unskilled workers in industry than among the general population.

The recognition of the need for intensive study in the field of industrial hygiene has resulted in the formation of a Council on Industrial Health in the American Medical Association. The importance of industrial hygiene has been realized, and a demand for studies and institution of preventive measures for the control and prevention of disease in industry has resulted in the establishment of bureaus or divisions of industrial hygiene in the health departments of twenty-six states and three cities.

There have been added responsibilities of the health departments in relation to certain diseases and crippling conditions. It is an indisputable fact that many of these diseases or conditions are of long duration, and many of those suffering from such diseases or conditions are unable to provide for themselves needed medical care and hospitalization. With the knowledge of the public concerning such diseases and conditions and with the death rates of certain diseases steadily increasing, it has been necessary for the functions of the health departments to be expanded in many instances in an effort

to meet this need. Certain diseases, such as cancer and heart disease, have steadily increased as a cause of death, and the health departments are receiving requests not only to furnish information and education which would lead to early diagnosis but even to provide facilities for treatment and care in cooperation with the medical profession.

These added functions and responsibilities of health departments can properly and successfully be carried out in the many fields which must be undertaken only with the coordination and correlation of the activities of those engaged in preventive medicine, industrial medicine and public health. The physician will continue to perform his duty to humanity as far as he is able to do so, but the care of the indigent sick is a responsibility which the physician cannot carry alone, and it is not his place to assume this responsibility without just compensation for his services. A satisfactory solution of the problem of medical service requires the development of cooperative plans between the medical profession and the official health agencies.

State Office Building.

AN EVALUATION OF THE THERAPY OF PEPTIC ULCER

CLARENCE F. G. BROWN, M.D.

CHICAGO
AND

RALPH E. DOLKART, M.D.

BOSTON

Present therapeutic efforts directed against gastroduodenal ulceration are an outgrowth of empiricism bolstered by laboratory experimentation which sometimes comes out in such a way as to confirm fixed ideas. From the standpoint of progress in medical management, one can summarize by saying that several dozen new variations in therapy have been introduced, enabling clinicians to obtain the unsatisfactory results of ten or twenty years ago by a greater variety of methods.

The early clinical work on peptic ulcer was, viewed in retrospect, purely of the trial and error variety. Its object seems to have been to find something which would alleviate the distress of the sufferer. This was finally accomplished by the frequent administration of alkaline powders. If insufficient relief was obtained, these powders were given every hour and, if the patient still complained, throughout the night. When this procedure didn't succeed, the stomach was emptied by tube from time to time and the barrage of neutralization resumed. This fundamental idea remained the same from the early days of Schwartz through Sippy's time and continues into the present. It became apparent to some observers, however, that the greater the amount of medication that was poured into the stomach, the more its secretions increased, the more irritable the gastric mucosa became and the greater was the spasm of the pylorus and ultimately of the large bowel. The formation of this vicious circle necessitated further refinements in efforts to neutralize the gastric contents, and substances less irritating than alkaline powders were substituted.

From the Department of Medicine, Northwestern University Medical School, and St. Luke's Hospital, Chicago.
Read before the joint meeting of the Section on Practice of Medicine and the Section on Pharmacology and Therapeutics at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.

To have any progress in ulcer therapy, one must find a way to induce the gastroduodenal mucosa to protect itself from ulceration. In approaching the problem from this aspect let us state as nearly as we can the etiologic factors associated with some 1,500 recurrences of ulcer observed in a carefully studied group of cases during the past fifteen years. It should be emphasized that the opportunities for observation were possible because of the recurrences. We hope that we have honestly evaluated them. In many instances it seemed quite plausible that the etiologic factors responsible for the recurrence were also responsible for the original ulcer. Functional nervousness, including fatigue and anxiety, was by far the greatest detectable cause of recurrence. Next in importance was an acute infection such as a cold, an acute sore throat, a sinus infection, an acutely abscessed tooth or acute gastro-enteritis. Of third consideration were the things put into the stomach by the patient, hamburgers and restaurant potato salad leading the list in foods, with salicylates and iron preparations prescribed by other physicians following closely. We are observing the effects of sulfanilamide and related substances with interest. The treatment of peptic ulcer must be guided by the causes and the predominating cause receive the major part of the therapeutic effort.

The problems arising in connection with the acute stages of gastroduodenal ulceration—perforation, hemorrhage and obstruction—are diverse but are not as difficult to treat as the chronic manifestations of the disease, because fewer alternatives in therapy are available. Perforation constitutes a surgical emergency as soon as diagnosed. Obstruction constitutes a surgical problem only when it is completely established that the retention is due to scar tissue formation, and edema and spasm have been ruled out by trial therapy with atropinization and aspiration and the lapse of time. This point has been well emphasized by both Means¹ and Lahey. Meulengracht² reported a mortality of 1.3 per cent in a group of 368 patients with massive hemorrhage treated medically with the administration of a full diet. This is by no means a new development, and the so-called Meulengracht regimen was used in 1890 by Lennhartz and also by Prebble and Gilbert some years later. Woldman³ has recently reported a group of twenty-one cases of massive hemorrhage treated with a continuous aluminum hydroxide drip. Finsterer⁴ and others advocate immediate and radical operation, although their mortality statistics are considerably higher. Bock,⁵ Marriott and Kekwick⁶ and Wood⁷ prefer a restricted diet and repeated blood transfusions. Still other clinicians employ starvation therapy. At present the weight of evidence suggests that the best results are obtained with an unrestricted bland dietary regimen. While this regimen has its merits, the final choice in therapy depends on the clinical condition of the patient. When there is a marked fall in blood pressure,

profuse diaphoresis, pallor and nausea, transfusion certainly should be employed. Recently we tried the hourly gelatin feedings described by Andresen⁸ and by Windwer and Matzner⁹ and obtained good results when mucin and frequent feedings had failed.

Various reports on the treatment of chronic gastroduodenal ulceration are difficult to interpret. Studies of results from different types of therapy used with the same group of patients have been comparatively few. Despite the great number of reports in the literature, therefore, there is little common ground on which to base a comparative evaluation. We shall review briefly and comment on the more commonly employed forms of ulcer management.

SIPPY MANAGEMENT

Traditional management, unmodified from the original plan of therapy described by Sippy, is probably not widely employed. Various dietary modifications together with efforts to neutralize the gastric contents with alkaline powders are, however, in common use. There is no conclusive affirmative evidence and there is considerable negative evidence regarding the hypothesis that complete neutralization of the gastric contents is the goal to be attained in treating a patient with ulcer. In our group of twenty cases previously reported,¹⁰ weekly gastric analyses were performed during the period of observation, which lasted on an average three and one-half years. Our data showed that the spontaneous trends of the free acid levels were unrelated to the type of therapy, that fluctuations in gastric acidity bore no definite relationship to the onset of a recurrence of ulcer and that there was no correlation between the height of the free acid level and the degree of distress manifested by the patient. Additional studies, in which fractional gastric analyses were performed for eight hour test periods, showed that complete neutralization of the gastric contents by alkaline powders was followed by a rise in the free acid to levels higher than those which existed prior to the administration of the alkali. This fundamental point was first shown by Carlson in 1916 but is still generally disregarded.

Perhaps the corrosive action of the gastric secretion plays some part in the formation of an ulcer and in the maintenance of its chronicity. It is our opinion, however, that in the efforts of clinicians to produce completely neutral stomach contents they lose sight of more important factors in ulcer management. In comparing the incidence of recurrences of ulcer in patients receiving Sippy management with the incidence of recurrence in the same and different patients while receiving other types of management, no significant difference in frequency was obtained. Forty per cent of the patients receiving alkaline powders and hourly feedings became worse in the eighth to twelfth week of treatment. Whether this was due to a dietary deficiency resulting from the restricted regimen, possibly an iron or vitamin deficiency, or to some other factor, we don't know. The more conscientious the patient in following the diet, the worse he did. Furthermore, alkalization is not without definite dangers. It has been alleged that the incidence of renal calculi in patients who have been receiving alkaline powders over extended periods is

far too high to be considered insignificant. Although alkalosis occurs less frequently when tribasic salts are used, it remains an ever present potential source of danger. In brief, hypersecretion and gastric irritation are produced as the price of hourly alleviation of distress, and the patient's general condition is harmed rather than improved. The condition of the sufferer from chronic ulcer is rendered more chronic and nothing constructive is accomplished.

COLLOIDAL ALUMINUM

Aluminum hydroxide and magnesium trisilicate preparations have come into extensive use to replace alkaline powders in buffering gastric contents without having the same untoward effects. Colloidal aluminum may be administered in large amounts without danger of alkalosis. Ivy has demonstrated that in dogs large amounts of aluminum hydroxide do not interfere with the activity of other digestive enzymes. In his laboratory, however, it was also shown¹¹ that the administration of large daily doses to normal dogs did not produce a decrease in the gastric secretory response to food, and on prolonged administration there was actually a compensatory increase in gastric secretion and acid in response to food when aluminum buffered test meals were given. While these two effects are undesirable, they are not as marked as in the case of alkaline powders. After careful clinical studies, Rutherford and Emery¹² recently reported twenty-eight cases of severe intractable peptic ulcer treated with colloidal aluminum which had been observed for long periods while other forms of therapy were being given. It is suggested that this treatment is advantageous when ulcer does not respond to other types of treatment because of marked hypersecretion. Patients whom we have observed made better progress than those receiving alkaline powders. There was less difficulty in controlling bowel function. There was no significant difference in the incidence of recurrence.

GASTRIC MUCIN

Ivy and his co-workers¹³ have demonstrated the prophylactic value of gastric mucin in the therapy of postoperative jejunal ulcers in Mann-Williamson dogs and in the prevention of ulceration in dogs with biliary fistulas. It is reasonable to suppose that mucin furnishes the needed material in a person whose mucus metabolism is deficient, as has been clearly shown by Fogelson.¹⁴ We are firmly convinced of the rationale of gastric mucin therapy. Much of the criticism of mucin which arose shortly after its introduction resulted from the presence of impurities with secretagogue action. Preparations now available have been largely controlled in this regard. The use of four daily doses totaling from 4 to 8 Gm., together with frequent feedings and the frequent administration of antispasmodics, has been more successful in our hands in reducing the incidence of recurrence than any other form of management.

VEGETABLE MUCILAGE

Vegetable mucilages were first introduced as sources of smooth bulk in the treatment of spastic constipation. We observed that patients with peptic ulcer and concomitant symptoms of irritable bowel who were treated for the latter condition with vegetable mucilage did so well that we gradually substituted this for gastric mucin in cases of less severe ulceration. We do not consider it as effective as gastric mucin. As an adjunct in the treatment of ulcer for controlling symptoms of irritable bowel and constipation, we find the vegetable mucilages extremely useful. For the past four and one-years we have had an opportunity to employ one of the preparations¹⁵ extensively in the routine treatment of bowel symptoms in cases of peptic ulcer in the outpatient clinic. Increasing the concentration of powdered milk in the mucilage has proved helpful in controlling the ulcer symptoms as well. At present we do not use liquid petrolatum or other lubricants for regulating bowel habits except in the presence of rectal disease. The importance of measures to relieve symptoms of irritable bowel cannot be overemphasized. The close correlation between bowel spasm, pylorospasm and associated distress due to ulcer makes these factors more important in the treatment of ulcer than a futile attempt to maintain neutral gastric contents.

PARENTERAL THERAPY

There are so many conflicting reports on the results of the treatment of peptic ulcer with histidine hydrochloride that one's credence is strained in attaching any therapeutic value to it. In our group of patients with duodenal ulcer, histidine injections were given as one of the treatments to which they were subjected. There was no reduction in the length of time a recurrence of ulcer persisted or subsequent alteration in the patient's course when the number of recurrences which occurred prior to the treatment with histidine were compared with the number which occurred after this treatment. Five control patients in the group who had no ulcers but who received ulcer therapy showed a psychogenic response which could be duplicated with any type of medication as long as it was administered hypodermically.

VACCINES AND FOREIGN PROTEINS

Vaccines and various types of foreign proteins have been employed from time to time as therapeutic agents. These are subject to the same criticisms that have been given to histidine. According to Sandweiss's figures, efforts to control ulceration by parenteral therapy are actually deleterious, since from 87 to 92 per cent of the patients have relapses by the end of the first year as compared with from 46 to 54 per cent treated with diet or surgical intervention.¹⁶

COMMENT

The chief efforts in the medical management of the chronic stages of gastroduodenal ulceration should be directed toward protection or improvement of the involved area of gastric or duodenal mucosa. This cannot be achieved as a routine by any one form of therapy. In the last analysis all measures should be designed to stabilize the intermittent peristaltic activity

15. Metamucil, prepared and supplied to us by G. D. Searle & Co., Chicago.

of the stomach and reduce pylorospasm. This permits the normal backwash of duodenal contents and a more normal emptying time of the stomach. The latter is especially significant as far as hypersecretion is concerned. The desired goal can be reached by different routes. The surprisingly good records made by patients treated with hourly feedings, relative reform from frantic, anxious living, and antispasmodic medication cannot be overemphasized too much. Curtailment of emotional excitement and of fatigue are as fundamental in any plan of ulcer therapy as are the medications prescribed. It is important that in one's zealotry to treat the ulcer one doesn't lose sight of the patient. We have attempted to adhere to the rule: treat first the patient, second the bowel and last the ulcer. Tranquillity, rest, a proper diet from the standpoint of frequency of feedings and vitamin content, and antispasmodics are of major importance. Powders, mucin, aluminum hydroxide and mucilages should be considered secondarily as adjuncts in therapy.

Regardless of intermittent reports to the contrary, we must confess that at the present time gastroduodenal ulceration must be considered as a chronic disease. The incidence of recurrence will not be lowered until it is recognized as such and patients are maintained under continuous observation like patients with diabetes mellitus or pernicious anemia. For example, we have found that 68 per cent of the recurrences of ulcer in our clinic occur during the spring and fall. By observing patients at regular intervals throughout the year and placing them under rigid medical management during these seasons as a prophylactic measure we have reduced the incidence of recurrence by approximately 15 per cent. For real progress in ulcer therapy one must devise ways of improving the gastroduodenal mucosa and reducing hypermotility and not stop at the surface of the problem in persisting with neutralization, which is impossible for even the most astute physician to achieve day and night for the life span of any person. Complete education of the patient so that he is adequate and at ease in his environment is a more permanent and satisfactory objective.

ABSTRACT OF DISCUSSION

DR. CHESTER M. JONES, Boston: I should like to suggest a slightly different approach to the subject, although it is fundamentally the same as that expressed by the authors. Aside from the treatment of perforation, obstruction, possible hemorrhage and the ever present malignant stomach, ulcer treatment should be considered under two headings: (1) treatment of the acute condition in an attempt to heal the ulcer; (2) measures to prevent recurrence. As far as the first is concerned, any form of therapy will work in most cases. The authors outlined measures that have been utilized, and they might have added many more. They all work for immediate results except in the most complicated cases. Alkali of course will work but it is no better than other methods. In some instances it is important to try all the methods or the method one is most familiar with. As a rule the simplest method is the best. It is easiest on the patient and also on the physician. Furthermore, it does not permit the physician to follow or draw fallacious conclusions as to the results of his therapy. I think this is the most important point. One uses this medication or that and then believes, because the patient is improved, that it is responsible for the improvement. In the natural history of the disease, if the patient is given a chance he will get better and his ulcer will heal. Measures to prevent the recurrence of ulcer are more difficult and, at present, an insoluble problem. There is no form of therapy which will guarantee a cure, and I think

it is best for the patient to understand this at once. It seems to me of utmost importance for the individual who has a peptic ulcer to recognize the fact that he has a chronic, incurable disease. That doesn't mean he can't live as a useful member of society; it doesn't mean that he can't be symptom free a good part of the time, but it does mean he has to recognize that the condition which produces symptoms from time to time must be managed rather than that he should expect a cure from this or that measure. No such cure exists at present. We don't know the cause of ulcer, although we speculate wisely about it. I like the arrangement stressed by Drs. Brown and Dolkart that the important therapeutic measures should include: First, frequent feedings, and one might add of simple foods, and it doesn't matter what type of simple food it is. Second—this possibly should be first—freedom from tension of every sort. That means fatigue, and it means emotional stress and strain. That is the most difficult thing to achieve but it certainly is the goal to aim for. Finally, medicinal measures, in which they have emphasized possibly mucin. I should like to add, because I think it is equally physiologic, the use of atropine in tolerance doses, doses that are just short of producing unpleasant symptoms. There is no doubt that antispasmodics do prevent possibly or ward off the recurrence of ulcer.

DR. WILLIAM H. OLMSTED, St. Louis: I agree with the authors and with Dr. Jones that it is the mode of living of an ulcer patient that is the most important therapeutic factor. There is no disease which better illustrates the necessary care with which a physician must go into the details of the mode of life of his patient, if the patient is to keep free from ulcer symptoms. I am particularly interested in dietetics and propose to give specific suggestions as regards the intimate diet of ulcer patients; that is, after his recovery from acute symptoms and with the purpose of avoiding recurrences. First of all he should be careful not to overload his stomach and to cultivate the habit of eating between meals, and especially he should beware of holiday food and alcohol. He should cultivate drinking milk or buttermilk instead of coffee and tea. He should avoid eating large servings of meat and should take it but once a day. He should carefully avoid highly seasoned foods, such as sausage, frankfurters, soups, peppery salads, Mexican dishes, mustard, horseradish, pepper, green peppers, catsup, tobasco, A-1 and other meat sauces. He should avoid too coarse breads or cereals, such as bran muffins and bran cereals, whereas whole wheat bread is allowed and recommended. He should avoid too much hot bread and take bread that is crusty, a day old is better, or toasted. He should avoid seedy vegetables and the skin of fruits. Instead of whole tomatoes, rather the juice. He should avoid cucumbers, radishes, green olives, raw celery, berries, coconut and nuts. He should avoid rich foods, such as mince pie, cream pie, layer cakes, plum pudding and fruit cake. What the ulcer subject should eat is characterized by the simple diet that the growing child should take, leaving out all those fancy and unnecessary foods I have listed. In proportion to which the physician goes into intimate details, as I have tried to illustrate by the patient's diet, and particularly as to his mode of living, will he succeed in treating the ulcer patient successfully and prevent ulcer from recurring.

DR. A. B. RIVERS, Rochester, Minn.: Physicians have gotten altogether too scientific in the treatment of ulcer. They are using all types of therapy. Every week brings some new form of fancy parenteral injection and what-not, and all of them miss the point. They are looking at the ulcer with greater concentration. They can't see the forest for the trees, and I think that the authors and Dr. Jones very well pointed that out. There are three stages very distinct in the treatment of peptic ulcer. First, the control of symptoms. This, as has already been said, can be accomplished by almost any method that changes to some degree the manner in which the patient lives, the food he eats. We are apt to misjudge the efficacy of all fancy methods of treatment. This does not mean that one shouldn't use certain methods that have been taught by Sippy and other authorities. The principle of the first stage in the treatment of ulcer is to do something to make the food intake bland, to keep the acids in the stomach as low as possible and to support the tissues. Give the patient some rest. Under

those conditions, regardless of what you shoot into his veins or hip or what-not, he is going to get comfortable. The trouble is, we stop there. The second stage is to give the ulcer an adequate chance to heal. Under the most perfect experimental conditions an ulcer will not heal in less than six weeks. One of the difficulties in having recurrences so often is that we stop short of the period of healing. When the patient becomes comfortable we are so cocksure that this is the thing that is going to cure him that we say "You go on back to your work. You are fine." Silly, because the ulcer is not healed. The patient may be comfortable because the acids are lower, the spasm mechanism is controlled and he hasn't had any drinks for a couple of weeks. The third requirement in the treatment of peptic ulcer is to attempt to prevent recurrence. That isn't as hopeless as we think. However, we must recognize that peptic ulcer is not a single disease. The cause of peptic ulcer eludes us because we are looking for one cause. There isn't any one, because it isn't even one disease. There are at least five diseases wrapped up in the thing called peptic ulcer. If we can recognize that and find out what particular thing is the important thing in the patient's disease, I think we can prevent recurrence.

DR. CLARENCE F. G. BROWN, Chicago: If these ideas could serve to stimulate clinicians and physiologists to approach the problem by at least two other avenues, we would consider our efforts worth while. In the thirty-five years of the "nothing but neutralization" approach, we have made little progress in trying to understand better the factors leading to the strengthening of the mucosa itself; mucin treatment is at least a beginning. In reducing the hypermotility, through teaching the patient how to stabilize his emotional equilibrium we feel that some progress is possible. There are other factors in the defense mechanism which must be clarified and at least not obscured by the "acid-ulcer" theory. If one subscribed wholeheartedly to this theory one would know all the answers and need no further investigation. This "acid-ulcer" concept is a beautiful and plausible structure, but in our study we found that it failed to furnish consistent etiologic evidence. We therefore believe that there are other protective factors the presence of which prevents ulceration when the patient averages 115 clinical units of free hydrochloric acid and the absence of which allows ulcer formation at an acidity of only 15. One of the purposes of this paper is to stimulate doctors first to remain open minded and secondly to think and work to find and ultimately control the unknown components in the protective mechanism. We appreciate Dr. Olmsted's very specific dietary suggestions. We also feel that a physician should be specific in his advice to the patient; teach him to think honestly and change his point of view toward his noxious environment, if you cannot entirely change the environment. The usual "do not worry" is not sufficient; we have to train them how to do it. It may be necessary to use the main therapeutic effort on the wife of the patient or to visit the chief officer of the company for which he works to explain what there is about the man's job that makes him have an ulcer. Knowing the patient's point of view toward his environment, plus knowing how the environment itself must be changed, often involves details just as painstaking as are the dietary directions.

A Profoundly Erroneous View.—There is, if I mistake not, a prevalent opinion that the medical man of the future is to be equipped as a physicist, as a chemist; that he is to have behind him an array of delicate apparatus and reagents with which exact measurement is to be made possible to him; and that in these directions the salvation of medicine is to be sought. If I am correct in my belief that such is a current view, then I would state emphatically that I believe it to be a profoundly erroneous view. It confuses two issues—the daily routine of the practitioner and the work of the special investigator. These stand apart: they always will stand apart. You cannot deal with masses of patients by using refined methods; repeatedly it has been tried; it always breaks down. The chief weapons of the general practitioner are today, and will remain, his own unaided senses; these are supplemented by a few simple devices.—Lewis, Sir Thomas: *Research in Medicine and Other Addresses*, London, H. K. Lewis & Co., Ltd., 1939.

INTRACRANIAL HEMORRHAGE IN THE NEWBORN

M. HINES ROBERTS, M.D.

ATLANTA, GA.

Cerebral hemorrhage in the newborn is unquestionably of common occurrence. The statistics from various clinics differ a great deal, depending on the care and the method of observation. Careful postmortem examination of stillborn babies and infants dying within the first few days of life indicates a very high percentage of lesions of the brain attributable to trauma during delivery. Ford¹ concludes that at least one third of all deaths occurring during the first two weeks of life are due to birth injury.

The routine examination of the spinal fluid of a large number of newborn infants studied consecutively reveals the fact that approximately 12 per cent of all infants exhibit blood in the spinal fluid.² Fortunately, only a small group of these children show clinical evidence of cerebral damage.

The prognosis of intracranial hemorrhage in those infants surviving the initial shock of injury is a problem about which there seems to be little unanimity of opinion. In order to determine definitely the ultimate outcome which one may expect among those children suffering with cerebral hemorrhage at birth, it is necessary first that a careful study at birth reveal without doubt the true nature of the pathologic condition and second that a continuing study be carried on by the same investigator over a period of at least ten years and possibly longer. Such conditions are not easily fulfilled. The diagnosis of the disease at birth is not always so certainly and so simply made as one might be led to believe. It is only necessary to study a series of charts from some large obstetric service in a private hospital to appreciate this fact. It will be found that frequently the data may be inadequate to justify the diagnosis; much more often it will be observed that infants exhibiting certain symptoms and physical conditions which most likely have been produced by injury to the brain at birth have been diagnosed as having atelectasis or asphyxia without sufficiently careful study to reveal the true nature of the disturbance.

Further, it should be stated that the establishment of the diagnosis in this condition cannot be left entirely in the hands of the house physician in charge of the nursery in a large obstetric service. His observations, in order to be accurate and of value in such a study, must be checked by one who has had long experience in studying such infants. This is particularly true in the examination of the spinal fluid. A lumbar puncture skilfully done is reliable in establishing the presence or absence of blood in the spinal fluid produced by cerebral trauma; it cannot be depended on for diagnosis when carried out by one relatively inexperienced. The absence of blood in the fluid does not rule out intracranial injury, nor does the presence of xanthochromia establish the diagnosis of cerebral hemorrhage. I have never seen a spinal fluid obtained during the first four or five days of life which was perfectly colorless, although the pigment may be so faintly apparent that it

From the Department of Pediatrics, Emory University School of Medicine.

Read before the Section on Pediatrics at the Ninetieth Annual Session of the American Academy of Pediatrics, May 17, 1939, System in Infancy, Childhood and Adolescence, 1937.

2. Roberts, M. H.: The Spinal Fluid in the Newborn with Especial Reference to Intracranial Hemorrhage, *J. A. M. A.* 85: 509 (Aug. 15) 1925.

is easily overlooked if the fluid is not compared with water. The existence of a definite xanthochromia, even in the presence of gross blood, does not necessarily mean intracranial hemorrhage if the puncture has been done awkwardly by one inexperienced in the procedure. Microscopic examination of the red cells in the spinal fluid and chemical examination of the supernatant fluid may be necessary to confirm the diagnosis of intracranial hemorrhage. Xanthochromia as a rule is entirely unrelated to intracranial hemorrhage.

These and many other factors make the diagnosis at times difficult and make studies of a large group of records of newborn infants in most hospitals, to say the least, open to considerable inaccuracy.

In surveying the files of any large children's hospital one finds a depressing group of cases variously diagnosed as Little's disease, cerebral spastic paralysis, cerebral atrophy, microcephaly and even cerebral maldevelopment, all of which are directly attributed to birth injury. In many instances there is a story of a difficult labor accompanied by some of the classic signs and symptoms of intracranial hemorrhage. On this evidence is based the diagnosis. In quite a number there may be no such story of difficulty at birth and yet, on account of certain physical and mental disturbances which are commonly recognized as the probable results of intracranial injury, these cases too are placed in this category. Care-

TABLE 1.—Intracranial Hemorrhage Due to Birth Injury in 19,052 Consecutive Deliveries, White and Negro

ful study of these children by the neurologist and neurosurgeon, with the aid of air injections into spine and ventricles, may reveal sufficient data to make us fairly certain that the pathologic condition with which we are dealing is the result not of injury but probably of maldevelopment or degeneration. It seems to me that too little attention has been given to these children. Physicians are prone on rather superficial evidence to place them in the scrapheap of cerebral birth injury, and why not? There is a story of probable injury at birth: the child was cyanotic and, according to the mother, had a convulsion and now two years later he presents some features which we have come to believe are typical of cerebral injury. Is this sufficient evidence for diagnosis? I am inclined to think it is not. The question arises Might not the cerebral maldevelopment be a cause of the dystocia and distressing symptoms at birth rather than the effect?

I am convinced that no study of this problem from the files of a children's hospital can give any true conception of the significance of cerebral birth injury and its importance in the child's physical and mental development. Only by following a sufficiently large group of children from the nursery to later childhood can we approach the answer to this problem.

An attempt at such a study has been made in the newborn service at Emory University. This service consists of a private pavilion in which the upper class of Atlanta's population is cared for, and a large Negro hospital in which approximately 1,500 deliveries occur each year. In addition, there are included infants born in another large private hospital of the city. These

combined services place the total number of deliveries studied at 19,052, of which 8,577 are white and 10,475 are Negro.

Unfortunately, we do not fulfil in all particulars the ideals set forth in this paper. The diagnosis of cerebral hemorrhage has not been carefully checked in every instance by a single observer. This, of course, is obviously impossible in a large private hospital. We have,

TABLE 2.—Deaths Occurring in 19,052 Consecutive Deliveries, White and Negro

	Total Number	Rate per 1,000 Live Births	Intracranial Hemorrhage	Estimated Intracranial Hemorrhage
White.....	164	19.1	34	41
Negro.....	248	33.2	43	87
Total.....	512	26.8	77	128

however, accepted only those cases for study which seem to meet unquestionably the usual standards for such diagnosis. It is probable that under our strict censorship a number of infants suffering from intracranial hemorrhage have been excluded. It is equally possible that an occasional instance of cerebral maldevelopment may have been included in the study. Practically every diagnosis has been substantiated by a spinal puncture done by a well trained pediatrician. However, this was not an absolute requisite. In two cases in the series the fluid was free of blood, but at autopsy the diagnosis was proved as definitely intracranial hemorrhage.

Table 1 shows the number of cases of intracranial hemorrhage encountered in the entire group of 19,052 consecutive deliveries, both white and Negro. A total of 132 infants was definitely diagnosed, only 0.7 per cent of the entire group. This figure is undoubtedly far too low, as adequate autopsies were infrequently done. If Bundesen's³ figure of approximately 25 per cent for intracranial hemorrhage in neonatal deaths is accepted, it will be seen from table 2 that instead of seventy-seven deaths from this cause there should be 128. If this estimated figure for deaths from intracranial hemorrhage is added to the number of cases of cerebral hemorrhage in which the neonatal period was survived, the total figure is 183, or an incidence of about 1 per cent in the entire series.

TABLE 3.—Causes of Death in 8,577 Consecutive Deliveries (White)

	Term	Premature	Total
Intracranial hemorrhage.....	27	7	34
Respiratory deaths, atelectasis-asphyxia	22	86	108
Others.....	23	0	22
Total.....	71	93	164
Stillbirths.....			74

Table 2 gives the number of neonatal deaths with the rate per thousand live births, the actual number of intracranial hemorrhage cases encountered, and the estimated number of deaths due to this condition. The comparative figures for the races are interesting, showing the relatively high neonatal death rate for Negroes.

Further investigation of the deaths from intracranial hemorrhage shows that, of the seventy-seven infants definitely known to have this condition, sixty-six died

3. Bundesen, H. N.; Fishbein, W. I.; Dahms, O. A.; Potter, Edith L., and Volke, Walter: Factors in Neonatal Deaths, J. A. M. A. 111: 134 (July 9) 1938.

before they were 72 hours old; only seven lived longer than six days. If the infant survives the initial trauma for three days, he probably will not die primarily of cerebral injury.

Table 3 gives in some detail the total deaths which occurred among the 8,577 white infants. These statistics are of importance chiefly in stressing the inadequate methods employed at the present time in deter-

mining the causes of death during the neonatal period. Owing to the fact that autopsies either were not done or were inadequately done, only fifty-six cases of 164 were accurately diagnosed; the remaining 108 were, in the main, classified as asphyxia or atelectasis, which diagnoses are of course entirely unsatisfactory.

Table 4 presents the same material for the 10,475 Negro infants. Of the 348 deaths only seventy-nine were accurately diagnosed; the remaining 269 cases were classified in the usual manner as atelectasis or asphyxia. This emphasizes the fact that until adequate autopsies are done on infants dying during the neonatal period and on the stillborn there is little probability of greatly reducing the mortality rates.

No study of the incidence of intracranial hemorrhage in the newborn can approach accuracy without a careful analysis of the stillbirths. Various observers have placed the figure at from 20 to 45 per cent and, in certain observations on the premature, as high as 80 per cent. A conservative estimate of intracranial hemorrhage in the stillborn is probably in the neighborhood of one third of such infants.

Table 5 shows stillbirths which occurred in the survey with the rate per thousand live births. If one accepts the figure already given as the probable incidence of intracranial hemorrhage in the stillborn, an additional 232 deaths must be attributed to this cause, bringing the total incidence (living and dead) to about 415, or approximately 2 per cent of all births.

Further consideration of table 5 brings out the fact that the stillborn rate among Negroes is tremendous, indeed so out of proportion to that of the white race that it is probably entirely inaccurate to estimate the number of cases of intracranial hemorrhage cases on the same basis in the two races. There is undoubtedly some very potent factor or factors at work in the Negro race which fail to militate against the white.

Table 6 shows the incidence of syphilis in the Negroes of this survey. Of the 10,475 deliveries, either the mother or the infant or both gave a positive Wasser-

mann reaction in about 1,853 instances, or 17.6 per cent. Known intracranial hemorrhage both in the living and in the dead showed only 21.6 per cent to be syphilitic, which would make it appear that the infection has little direct influence in producing the pathologic condition. In that group of infants dying of "atelectasis and asphyxia," it is probable that syphilis was the true cause of death in one third of the cases.

Table 7 is a comparative study of the incidence of intracranial hemorrhage in the two races. As explained before, these figures are undoubtedly low and, if proper correction should be made for the large group of neonatal deaths from unknown causes, the figure would probably lie somewhere between 1 and 2 per cent of all deliveries. One interesting difference in the figures is the very small number of Negro infants who appear to survive the neonatal period. Only about 30 per cent of the Negro infants suffering with cerebral hemorrhage survived, whereas more than 50 per cent of those infants lived in the series of white cases.

The significance of the weight of the infant at birth as related to birth injury has been stressed by other writers. In this series thirty infants were overweight, fifty-seven were of average weight and thirty-two were small babies.

A study of the parity shows that seventy-two of the infants were born of primiparous women and thirty-nine of multiparous.

The character of the labor in this series indicates that thirty-eight infants were born by labors described as normal, whereas seventy-nine were abnormal in some respect, such as forceps deliveries, breech presentation or some other operative procedure.

In table 8 are shown sixty-six cases of intracranial hemorrhage due to birth injury which have been followed for varying periods of time in an attempt to determine what the ultimate outcome may be. In evaluating these figures we must keep in mind what has already been stressed: the possibility of errors in

diagnosis at birth. However, since we have thrown out a considerable number of cases which were probably cerebral hemorrhage but which we felt could not be diagnosed with certainty, it is likely that few if any cases have been included which were due to other pathologic processes.

The following criteria were used as a basis for diagnosis: In most instances there was the history of a difficult labor which would naturally predispose to injury; most of the infants were resuscitated with

difficulty, cried 'poorly' (if at all), were cyanotic, and in every case showed evidence of motor irritation either by local or generalized "twitchings" or outright convulsions; the spinal fluid in practically every instance showed the presence of blood, which was interpreted to have arisen from a preexisting pathologic condition and not due to trauma resulting from the lumbar puncture.

The picture gained from this summary is a bright one. Forty, or about 60 per cent, of the entire group seem perfectly normal today. These children have been followed for an average of five and a half years, none less than ten months, fifteen less than five years and several from twelve to fifteen years. Of course, those observed only a year or two may yet show some residual sign. Certainly, however, they will not suddenly develop the typical picture of cerebral spastic paralysis at some later date.

TABLE 8.—*Intracranial Hemorrhage in the Newborn: Prognosis in Infants Surviving the Initial Shock of Injury*

Total Number of Cases Observed, 66			
A*	B*	C*	Infants Observed Less than One Month
Normal	Motor Disturbance	Motor and Mental Disturbance	
40	4	10	12

* Average number of years followed: A, $5\frac{1}{2}$ years; B, 8 years; C, 3 years.

Fourteen of these cases have shown some definite motor or mental disturbance, or both. Only nine can be classified as cerebral spastic paralysis, showing both motor disturbance and mental retardation. The four cases showing only motor disturbance consist of two monoplegias, a paraplegia and one showing general spasticity and incoordination of all extremities, although the mentality is normal for the child's age.

Of the twelve children not followed it seems reasonable to suppose that at least seven, or 60 per cent, are perfectly normal today, which would bring the total figure for normals almost to fifty.

It is interesting to note that only two of the children showing motor and mental disturbance are Negroes. This observation bears out the impression I have gathered after working for many years with Negro children: that typical cerebral spastic paralysis is extremely rare in this race. A search of the files in a large Negro pediatric outpatient clinic reveals only five cases which might be so classified. There may be a definite relationship between this observation and the fact that apparently the incidence of cerebral anomalies, as is true with certain other anomalies (particularly those of the gastrointestinal tract and the heart) is much less common in the Negro race. This may prove another link in the evidence that many so-called "residuals of birth injury" in reality may be cerebral anomalies.

CONCLUSIONS

Intracranial hemorrhage in the newborn is of common occurrence. It manifests itself clinically in from 1 to 2 per cent of all infants. About 85 per cent of all babies who fail to survive the initial shock of birth injury die within the first three days of life. After this period it is not probable that intracranial hemorrhage will be the direct cause of death.

Of the infants who survive the initial shock of birth injury, approximately 75 per cent will develop normally.

Relatively few will develop the typical features of Little's disease or cerebral spasticity.

It seems likely that a large number of cases of so-called cerebral spasticity are not due to birth injury but probably are attributable to degeneration or maldevelopment.

ABSTRACT OF DISCUSSION

DR. RALPH M. TYSON, M.D., Philadelphia: Dr. Roberts has brought to our attention an important problem in the care of newborn infants. The low mortality rate presented apparently indicates that good obstetrics as well as good pediatrics is being practiced. I am interested to know whether the information given is based solely on the cases that came to autopsy or whether it is a combination of clinical and autopsy material. The large number of premature Negro infants dying of what is spoken of as "respiratory conditions" seems to me might have been confused with cases of intracranial hemorrhage. The small premature infant is particularly liable to intracranial damage. The clinical diagnosis of intracranial hemorrhage is not easy to make and I doubt very much whether the criteria suggested by Dr. Roberts will fit all the cases. So many other conditions present clinical symptoms resembling intracranial hemorrhage that the real diagnosis cannot be made except by careful postmortem studies. Hemorrhage into the brain substance, if large, may cause porencephaly or may be small from anoxemia. The location of either large or small hemorrhages has a great deal to do with what symptoms are produced and perhaps in neither one would blood be found in the spinal fluid. Edema of the brain, a condition that is occasionally found in autopsies of the newborn, may produce similar symptoms. Again in this condition no blood will be found on spinal puncture. More careful studies of the brain at autopsy are revealing the fact that maldevelopment is more frequent in occurrence than we have believed heretofore. This condition again produces symptoms resembling injury. I fear that in the past many obstetricians have been falsely accused of poor obstetric technic because of such cases. Even pyelitis in the newborn, while rare, may produce symptoms resembling intracranial injury. In work with the newborn child in Philadelphia, one of the biggest difficulties to overcome is the lack of accurate clinical observation and sound judgment in arriving at decisions relative to the cause of death. Heretofore atelectasis, congenital heart disease and intracranial injury have been the choice leaning props for the physician who is not able to make a true diagnosis. Undoubtedly our knowledge of intracranial hemorrhage, especially in the dead infant, will be satisfactorily accurate when autopsies are done on all infants by some one who is not only skilful but who is also very much interested in the problem.

DR. HUGO EHRENFEST, St. Louis: I can speak on the subject only from the standpoint of the obstetrician. The paper includes a series of injuries observed in Negro children and discussed from the angle of a possible syphilitic aspect of the question. I don't know of any previous statistical investigation in regard to this point, though among the many writers on the subject only the French assert that syphilis does play an important role in the causation of these injuries. In this respect the author's contribution is noteworthy. I agree with practically everything Dr. Roberts has said, but I do not quite agree with the title of his paper. Though it refers only to "cerebral hemorrhage" he and also Dr. Tyson spoke of intracranial birth injuries in general. These are not synonymous terms. The obstetrician realizes that the baby's head is likely to become traumatized during labor and there probably is a definite amount of "physiologic" damage. Traumatization obviously varies within wide limits, from one hardly noticeable up to traumas resulting in extensive hemorrhage. The "hemorrhage" represents only a special type of injury and thus more precisely one can discuss either traumatization in general or hemorrhages in particular. The problem of birth traumatization and intracranial damage is a broader and wider one. The human fetus is the only mammal that has not a rigid skull but one in which the various bones are only loosely connected with one another.

The human fetal skull has to change its configuration as it passes through the bony pelvis. It is enabled to do this on account of incomplete ossification, which leaves the flexible sutures and fontanels. Compression of the head in one direction always causes a corresponding lengthening of diameters in the perpendicular direction and therefore there is no noteworthy actual reduction in volume. Excessive and long continued pressure may cause anemia and degenerative processes. With sudden expansion there may develop an acute edema of the brain, but the nature of intracranial damage is chiefly determined by the stress on dura folds during molding. When the pediatrician desires exact information concerning labor he should not have to ask the patient. The obligation rests with the obstetrician to note in his records how the newborn baby behaved immediately after birth and for the next few days, whether it breathed or cried immediately, how much effort was required to initiate respiration, whether there was noticed any jerking of extremities, convulsions or interruptions of breathing, and so on. All this information should be on the obstetric record. It is invaluable for the pediatrician or neurologist who many years later has to decide whether a physical or mental defect may be connected with a possible intracranial damage sustained at birth.

DR. JULIUS HESS, Chicago: There has been a premature infant station at the Sarah Morris Hospital in Chicago for seventeen years. During that time 3,148 premature infants have been admitted to the station. Of those, 887 have died. We have been able to obtain autopsies on 774, and in 42.7 per cent of these there were more or less massive intracranial hemorrhage, a very high percentage involving the ventricles and the cortex. Dr. Ehrenfest raised the question of physiologic trauma. That undoubtedly is a large factor in the premature. In our own cases our highest percentage was seen in the breech deliveries, both spontaneous and by extraction. Cesarean sections were second. Probably the most interesting thing that has come out of the study is that brought out by Dr. George Mohr, psychiatrist, and Dr. Phyllis Bartelme, psychologist, who were lent to us for four years by the Institute for Juvenile Research of Chicago. They selected 250 among our oldest graduates. At that time, in 1929, some of them were already 7 years of age, and others were as old as 11 before the study ended. We tried to locate every case in which there was a history of intracranial hemorrhage. A goodly number of those who did not show evidence in the station were found to have some evidence when they returned to the follow-up clinic which made us believe that they had had hemorrhage. We located sixty-nine cases, and of those eleven showed very serious evidence of cerebral involvement. Of the eleven, seven showed marked mental retardation. Of the group with moderate evidence, seven in number, four showed considerable mental deterioration; and in nine mild cases with increased reflexes, strabismus or other minor changes, two showed mental deterioration. In other words, it would have been better if thirteen of sixty-nine among 975 graduates at that time had not survived. Forty-two of the group showed no evidence whatever of intracranial hemorrhage. The work of Dr. Abraham Levinson and Dr. Otto Saphir, clinician and pathologist of our institution, has given us some evidence as to why so many of those sixty-nine, forty-two in number, did not show evidence of trouble. They found, on studying the autopsy material in infants who lived for a considerable number of days or months after birth, that there was very little evidence of organization of the clot. In most instances the original clot, or blood, had been largely absorbed.

DR. M. HINES ROBERTS, Atlanta, Ga.: It is important that every newborn infant receive a careful physical examination at birth, with accurate observations of his behavior from day to day. In my experience, especially in large private hospitals, the newborn infant does not receive this service. Not until he is given the same careful study as that devoted to the older child and adult in any well equipped hospital will true progress be made in diagnosis and treatment of neonatal disorders. The problem of adequate autopsies on infants dying in the neonatal period, and on the stillborn infants, is still one far from solution, even in many of the best obstetric services. In order to influence these mortality figures favorably, it is essential that correct diagnoses be made. Only by careful autopsies can this

be done. In reply to Dr. Tyson's question as to whether autopsies were done on infants dying from intracranial hemorrhage in this series, I should like to repeat that in practically every instance the diagnosis was confirmed in this manner. As stated before, in that large group of infants dying with so-called atelectasis or asphyxia, it is probable that 25 per cent would have shown intracranial damage had autopsies been done. Dr. Hess's figures are very interesting and seem to coincide closely with those presented in this study. He states that of the sixty-nine proved cases of intracranial hemorrhage forty-two were found to be normal, whereas, in the group presented to you this afternoon, forty-four of the sixty-six so diagnosed are perfectly normal today.

THE POTENCY OF DIGITALIS PREPARATIONS OF THE 1936 PHARMACOPEIA

CHARLES W. EDMUNDS, M.D.

Professor of Materia Medica and Therapeutics, University of Michigan Medical School; Chairman of the Committee on Bio-Assays of the United States Pharmacopeia

ANN ARBOR, MICH.

During the past two or three years, several papers and other communications have appeared in medical and pharmaceutical journals calling attention to the increased potency of the digitalis of the Pharmacopeia of 1936 (eleventh revision) as compared with that of U. S. P. X. While the relative potencies that are named in these papers differ among themselves, several of them state that digitalis of the eleventh revision (1936) is from 150 to 170 per cent of that of the tenth (1926) revision. The statement that the official drug of today is stronger than that of ten years ago is true, and there remains to be determined only the approximate increase in this potency.

Before I take this up for consideration it may be well to explain the reason that led to this change in the official requirements. This action was taken primarily to bring about through international agreement a greater degree of uniformity in the strength of certain important drugs and preparations as they are employed in different countries. Much had been accomplished in this direction through the Brussels conferences and the establishment of the "international protocol standards." In addition, in the middle twenties conferences were held under the authority of the Health Committee of the League of Nations, the special object being to consider the adoption of international standards for digitalis and certain other drugs and biologic products for which no uniform method of standardization was available. At the 1925 conference, held in Geneva, a composite powder of digitalis obtained from different sources was adopted as the international standard, and the different countries were urged to make their own national standards conform to the potency of this blended powder. The United States Pharmacopeial Committee of Revision, therefore, adopted this international powder as a standard in the eleventh revision (1936) and authorized the preparation of a standard for this country, its potency being determined in relation to the international powder. I undertook the responsibility of the task, being assisted in the work by Drs. Moyer and Shaw. The powder itself was secured by Professor Cook, chairman of the Revision Committee, and was a mixture of the drug obtained from three sources, two thirds being of American growth, one sixth from England and one sixth from Switzerland.

It will be seen at once that there are two questions involved: first, the relation of the potency of the international standard to the U. S. P. standard of 1926, i. e., ouabain; second, the relative potency of the U. S. P. XI reference or standard powder to the international powder. In the study of the first question it became at once apparent that the U. S. P. digitalis of 1926 was relatively weaker than the international powder, which in itself, being a blend of ten powders, was considered to possess only average strength. Manufacturers who were consulted all said there would be no difficulty in meeting the strength of the international powder, as practically any good drug on the market was of higher strength than the U. S. P. X demanded. For a direct answer to the question, studies which were carried out in this and other laboratories indicated that, as measured against the old U. S. P. X standard ouabain, the international powder was from 125 to 130 per cent of the pharmacopoeial requirement of that day. For example, we¹ found by the official method of assay that 1 Gm. of the international powder was equivalent in potency to 1.1 mg. of ouabain, while 1 Gm. of U. S. P. X powder was standardized to equal 0.833 mg. of ouabain. Thus the former was 132 per cent of the latter. Rowe² found as a result of five assays a relative activity of 123 per cent for the international standard powder as compared with the U. S. P. X standard, and Smith³ reported a similar figure of 125 per cent by the cat method.

Thus, based on the international standard, the U. S. P. digitalis powder and tincture since 1936 have been from 25 to 30 per cent stronger than that which had been in use previously. This fact should be clearly understood by all physicians who use digitalis preparations conforming to the U. S. P. standards.

With the first question answered, the main point of the present difficulty was to ascertain how accurately this relative potency of the new digitalis to the old had been achieved. The answer to this question is to be found in the accuracy of the assay of the U. S. P. reference powder in relation to the international standard.

Using the official U. S. P. method of assay, Edmunds, Moyer, and Shaw⁴ showed that when this method was employed 0.744 Gm. of the U. S. P. powder was equivalent in potency to 1 Gm. of the international powder. The accuracy of this figure was tested by checking and rechecking the results as enumerated in the original report and finally by preparing alcoholic macerates of the two powders, using 1 Gm. of the international standard powder and 0.744 Gm. of the U. S. P. powder. An assay of these two macerates showed that the potency of the one prepared from the U. S. P. powder was 105.9 per cent of the international standard. These results would indicate that within the limits of error allowable in bio-assays a factor of 0.745 is approximately correct for the U. S. P. reference powder. We confirmed these observations further by assaying the two powders by the four hour frog and the lethal dose methods of assay, employing the appropriate factors in each instance. The results of all these assays carried out on different lots of frogs and at different times

of the year did not show a variation from the theoretically perfect 100 per cent of over 6 per cent.

Confirmation of the correctness of this factor (0.745) has been received very recently from Dr. K. K. Chen,⁵ who has had wide experience in carrying out the assay of digitalis according to the U. S. P. method. He reports that, following the U. S. P. requirements and using the proper factor for the U. S. P. reference powder, he made between March 23, 1936, and Dec. 14, 1938, twenty-three comparative assays of ouabain, U. S. P. X digitalis and U. S. P. XI digitalis, carrying out the individual assays of the two powders and of ouabain on the same days. The average of all his assays showed a potency of U. S. P. XI digitalis of 126.6 per cent as compared with U. S. P. X. Fifteen of his assays showed a value between 120 and 130, and only three were over 140 (143, 143, 146). In connection with Dr. Chen's results it is noteworthy that the average of the results of Edmunds, Lovell and Braden,¹ Rowe² and Smith,³ namely 132, 123 and 125 per cent, is 126.3 per cent.

Coming now to the cause of the conflicting reports of the potency of the 1936 product it may be pointed out that, in the original preparation of the U. S. P. standard and in the establishment of the necessary factor, great care was used in the conduct of the assays to control as far as possible all the conditions which might have an influence on the results, as it was realized that as soon as the standard was released workers over the country would be rechecking the results, and comments on them would not be long in reaching the medical and pharmaceutical press. Apparently this thought has been realized, and it is my purpose to consider as briefly as possible the three or four papers around which the storm seems to center and to try to locate the cause for the difference in results which has led to the difficulty.

For convenience it might be well to consider first the work by Fahr,⁶ since this communication seems to have been the first to call the attention of the practicing physician to the increase in potency of the U. S. P. XI digitalis. Discussion of this paper is rather difficult, as two methods of assay are involved, viz. the one hour frog method and the cat method, and Dr. Fahr in his footnote 5 and in the body of the paper proper, while speaking of cat units, converts results from the frog assays into cat units when he takes the 170 per cent potency reported to be obtained on frogs and makes his cat unit therefore equivalent to 0.065 Gm. instead of the generally accepted 0.100 Gm. of digitalis. In considering this figure of 170 per cent it is necessary to examine the letter of Dr. Wright,⁷ as he assayed the digitalis for Dr. Fahr, using the frog method. Wright points out that the U. S. P. X (1926) standard for digitalis required 600 mg. to kill 1 Kg. of frog but that the reference powder of U. S. P. XI (1936), according to twenty assays carried out by him over two and a half years, required only 350 mg., thus giving it a potency of 170 per cent in relation to the U. S. P. X digitalis. Fahr, accepting in general the figure of 170 per cent reported by Wright, sets his cat unit at 0.065 Gm. but in doing so prefers to accept the finding of Edmunds, Moyer and Shaw⁴ of 391 mg. instead of Wright's 350 mg. This difference is of minor importance, as neither figure should have been

taken, and therein lies the whole trouble. The figure of 391 mg. obtained by Edmunds, Moyer and Shaw⁴ (and also the 350 mg. of Wright) is for the toxicity of the reference powder itself and not for the U. S. P. standard. It is well known to all who have worked with this powder that it is stronger perhaps than it should be, and the work of Edmunds, Moyer and Shaw,⁴ as already mentioned, established a factor of 0.745 for it, as compared with the 1 Gm. of the international standard for the U. S. P. digitalis unit based on it. If Wright had used 0.745 Gm. as directed instead of 1 Gm., his results would have been very different. While the 350 mg. finding does give a percentage strength of 171 as compared with the U. S. P. X, if the correct amount of the reference powder, viz. 0.745 Gm., had been used he would have a relative percentage strength of 127, which agrees with our estimate of from 125 to 130 per cent.

The second point of difficulty in this paper lies in the use of the term "cat unit," a matter which will be discussed in a later paper. In the footnote mentioned Fahr says that the unit is determined "under the standard conditions of the original Hatcher-Brody method" and further that the unit "by other methods such as the Magnus modification differs considerably." Strangely enough after these statements it appears that Fisher,⁵ who made the cat assays for Fahr, does not use the original Hatcher-Brody method at all but the Magnus method or some modification of it, as he has dropped the use of ouabain employed in the original method, using digitalis only. Again Fahr goes on to say that "digitalis is standardized according to U. S. P. XI so that 0.65 cc. of the tincture or 0.065 Gm. of the powdered leaf is one Hatcher-Brody cat unit." This statement is misleading, as the U. S. P. does not mention "cat units" or recognize them in any way. Furthermore, there has not been sufficient study of the relationship between the results obtained by the two methods to make it safe to convert U. S. P. digitalis units into cat units. And yet that is apparently what the author does when he converts the erroneous figure from the frog method into Hatcher-Brody cat units.

To summarize the results in this paper, it appears that when the assay calculations are corrected by using the proper factor they confirm my views that the potency of U. S. P. XI digitalis is from 125 to 130 per cent of the U. S. P. X product; at least there is nothing in the Fahr paper or the associated letter of Wright to prove the contrary.

In certain of the papers that have been written on this subject and in which an excessive potency for U. S. P. XI digitalis is claimed, it may be frankly stated that I have been unable to put my finger on the cause of the discrepancy in results, as in most instances the details of the assay are not given, and it is variations in technic that explain many of the differences found. The paper of Rowe and Pfeifle⁸ falls into this category. As a result of eighteen comparative tests of the U. S. P. standard and ouabain by the one hour frog method, they report in their March 1938 paper that U. S. P. XI digitalis is 151 per cent of the U. S. P. X standard, while in the October 1938 paper Rowe⁹ reduces this figure to 140 per cent. In the earlier paper, in which a figure of 151 per cent is claimed, it is noteworthy in table I in which U. S. P. XI digitalis is compared

with the U. S. P. X ouabain standard that the assays on which the figure (151) is based show strikingly variable results in percentages—from 108 to 186, 188 and even 191 per cent. If a figure somewhere near 108 is correct, what shall be said of the 188 and 191 results or vice versa? Clearly such widely divergent results would call for a careful checking of technic.

In order to study the matter further, Rowe and Pfeifle⁸ also assay the international standard—the U. S. P. powder and the Canadian and British standards by the twelve hour or lethal dose method (table IV, page 186). The results of these assays again show that apparently the U. S. P. reference powder is 142 per cent of the international standard. In these assays, however, a most interesting fact appears. In the preparation of their solutions for the assays they use the correction factors to yield tinctures of the same potency as the international on the strength of which the factors are based. But a vital error was made in the case of the U. S. P. powder. Here they use the factor appropriate for the one hour method (0.745) in place of the twelve hour factor (0.5224). This error changed the whole relationship, as is seen in the accompanying tables, the first column of which is taken from the Rowe-Pfeifle paper of March 1938:

The figures in table 1 of the Ann Arbor group for these powders are given in column 3 and are uncorrected or absolute figures for the relative value of the powders, and these are recalculated in column 4, the appropriate factor being used for the twelve hour method. In column 2 the Rowe-Pfeifle figure for the U. S. P. powder has been corrected, the proper factor (0.5224 instead of 0.745) being used for the twelve hour method, and it is seen at once that the Rowe-Pfeifle and the Ann Arbor values for this powder agree exactly, so that using the correct factor Rowe's own figures show that the U. S. P. XI reference digitalis properly adjusted is uniform in potency with the international standard, basing this conclusion entirely on Rowe and Pfeifle's own figures when their error is corrected. Again, in the papers that Rowe and his associates¹⁰ have published on the general subject of the assay of digitalis they have repeatedly insisted on the superiority of the lethal dose method over the one hour official method. Without going into that question, it is interesting to note that their confirmation of our figures is obtained by the method which they themselves prefer. Finally, attention should be drawn to table VI of the Rowe-Pfeifle paper, in which the results that are obtained by the one hour frog method are tabulated. In table 2 are given in milligrams the mean systolic dose per kilogram of frog for the international powder and for U. S. P. XI reference powder and in the second column are the percentages calculated from the Rowe-Pfeifle figures, although these percentages are not given in their paper.

Here again from Rowe and Pfeifle's own figures we have confirmation of the accuracy of our results.

The report by Munch¹¹ is often quoted as authority for the claim that U. S. P. XI digitalis is 155 per cent of the U. S. P. X product. This is a brief report of a study made in the course of an investigation of a tincture of digitalis which was about eight years old. It was assayed in five laboratories in two different years. The results are rather typical of those seen in such cooperative studies, in which each worker varies

the assay according to his wishes, so that in this instance the ratios of activity run from 110 per cent to 213. Such a wide spread of results in itself casts much doubt on the results. If 110 per cent is approximately correct, what about 213 or vice versa? One laboratory reported a potency in 1936 of 90 per cent of U. S. P. X and 160 per cent for the same tincture in 1937 and a similar percentage increase when tested against the U. S. P. XI standard. No other laboratory presented figures approaching these. Briefly, in the absence of further details as regards technic and in view of the marked discrepancies, the report cannot be said to add to our knowledge of the question. In fact it is

TABLE 1.—Results of Assays of Digitalis

	Rowe and Pfeifle U. S. P. Powder Calculated		Edmunds, Moyer & Shaw	
	By Use of Incorrect Factor 0.745	By Use of Correct Factor 0.5224	Uncorrected Figures	Corrected by Factor 0.5224
International standard considered as.....	100%	100%	100%	100%
U. S. P.	142%	99.3%	191%	100%

more likely to confuse the issue, as the statement of excessive potency is quoted as an average of widely divergent figures, some of which are obviously incorrect, and without an examination of the figures which underlie the statement.

The study by Ichniowski and Thompson¹² is an important contribution to the subject of the assay of digitalis, although as it appears in the *Journal of the American Pharmaceutical Association* it is merely an abstract of a thesis presented as part of the requirement for an advanced degree. The last portion of the paper gives a comparison of the potency of certain digitalis extracts when related to U. S. P. X and XI. The preparations were assayed against ouabain, the standard employed in U. S. P. X, and against the U. S. P. XI powder, with the conclusion drawn that the U. S. P. XI digitalis potency is 153 per cent of the U. S. P. X potency. In table X of the paper three assays of the unmodified U. S. P. powder are assayed against the same powder adjusted to proper strength by employing the factor 0.745, and in each instance the results show that the former is 134 per cent of the latter. Our results⁴ give it an assigned value of 134.22 per cent. Two assays of the Canadian powder show that it is 115 per cent of the U. S. P. standard, which practically agrees with our finding of 115.77 per cent, ignoring the slight difference of 3 mg. in the factor of the two Canadian powders. These assays of the Canadian powder, which were made against the U. S. P. XI reference powder with the proper factor, then agree with our results. The other items in table X are various digitalis extracts on which I have no figures, so that a comparison is impossible. With the accuracy of technic and of the assay method attested by the results of the assay of the unmodified U. S. P. powder and of the Canadian powder, the explanation of the high ratio of potency of 153 must be sought in the assays carried out against ouabain—the standard of U. S. P. X. Here one is struck at once by the statement that the U. S. P. reference power is 200 per cent of the U. S. P. X standard. This figure is exceedingly high, in fact higher than has been reported by any other worker so far as I know. This figure is based on four

assays in which 100 mg. of the U. S. P. powder were found to be equivalent in potency to 0.168 mg. of ouabain, whereas the standard equivalent for 100 mg. of the 1926 digitalis was 0.083 mg. There are no figures in which the U. S. P. reference powder was compared directly with ouabain, but there are such figures for the international powder, and then, when one knows the relation of the U. S. P. to the international standard, it is easy to make the computation.

In our original study¹ of the international powder we found that 100 mg. was the equivalent of 0.11 mg. of ouabain, a finding essentially confirmed by Rowe² and by Smith.³ The U. S. P. reference powder being 134 per cent of the international, 100 mg. of the U. S. P. reference powder would be the equivalent of 0.147 of ouabain, and its relative potency to the U. S. P. X would be 177 instead of 200, as claimed in table X. On the basis of this, the U. S. P. XI standard is 132 per cent of U. S. P. X. Such a relationship would bring the Ichniowski-Thompson results into entire harmony with the others quoted, obtained either directly or by recalculation.

Finally, a report made to the American Drug Manufacturers Association by Taylor,¹³ chairman of the Committee on Digitalis, at its 1938 meeting, may be quoted. Taylor sent to each of ten laboratories an ampule of the international powder and one of the U. S. P. XI reference powder, asking that the two be assayed according to the official method in the U. S. P. XI with the appropriate factor of the U. S. P. powder, which of course makes the U. S. P. unit of the same strength as the international. Five of the laboratories reported an average strength of 101.3 per cent, or within 1.3 per cent of theoretical perfection. The other five had various results ranging from 107 to 136, averaging 134.9 per cent. The unanimity of the first five workers far outweighs in importance the results of the second group. The same difficulties and discrepancies which have been seen in all the previous cooperative assay results again creep in here, and I cannot help but endorse the sentiments expressed by Beal¹⁴ in discussing the same report that "we need some method of investigating the investigators" in order to see what variations are made in the technic

TABLE 2.—Percentage of International Standard

	Milligrams Systolic Dose per Kilogram	Percentage of International Standard
International standard 1926.....	610	100
U. S. P. XI.....	463	133.7

of the assays and which are accountable for the great discrepancies in results. Such departures from the prescribed technic doubtless are responsible for the discordant results of the cooperative report just quoted (as well as for the discrepancies in the Munch report quoted earlier), in which five workers come within 2 per cent of the theoretical figures while the other five range all the way from 107 to 136 per cent. It does not seem to be realized that it takes just as much experience, skill and attention to details to make an assay by biologic means as by chemical.

In the present study it has been conclusively shown that just such mistakes have been responsible for most,

have been administered. Depression of the bone marrow in this case lasted longer than usual.

CASE 5.—A white woman aged 57 was admitted to the hospital because of erysipelas of the face. The white blood cell count was 11,000 per cubic millimeter, 58 per cent of the cells being polymorphonuclear leukocytes. The red blood cell count was 4,250,000 per cubic millimeter. During the next three days the patient received a total of 15 Gm. of sulfanilamide. No other drug was administered. The use of the sulfanilamide was discontinued when the white blood cell count was found to be 3,000 and the red blood cell count 3,500,000. In the next three days the number of leukocytes dropped to 2,000 per cubic millimeter, 75 per cent of the cells being lymphocytes, and the erythrocytes to 2,500,000. Despite these blood changes the patient had no complaints except weakness. Her general condition was good. No ulcerative pharyngitis developed. She was given 40 cc. of pentnucleotide daily for five days and 10 cc. of liver extract daily for six days. The leukocytes started to increase in number and granular cells gradually reappeared but improvement was slow. When the patient left the hospital three weeks later the leukocytes numbered only 4,200 per cubic millimeter, but 63 per cent of the cells were polymorphonuclears.

Another case of granulocytopenia again illustrates that drug fever may precede more serious complications and that granulocytopenia may appear several days after the use of sulfanilamide has been discontinued, at a time when complications are not expected:

CASE 6.—A white woman aged 22 received sulfanilamide because of a puerperal endometritis. The white blood cell count during the first nine days of treatment varied between 11,000 and 16,000 per cubic millimeter. After sulfanilamide had been given for seventeen days, the patient having received 100 Gm. of the drug, it was thought that the temperature was remaining high because of the drug rather than the infection, which was much improved. This was true, for when the administration of the drug was stopped the temperature fell from 40 C. (104 F.) to normal in forty-eight hours, and by the following day the patient was asymptomatic. The next day, however, the temperature started to rise and reached 41 C. (105.8 F.) within the next forty-eight hours. The patient was acutely ill and, in the belief that she had a recurrence of her infection, therapy was resumed, the blood not being examined at this time. In the next twelve hours 15 Gm. of sulfanilamide was administered, after which the red blood cell count was found to be 3,000,000 per cubic millimeter and the white count 400, all lymphocytes. The use of the sulfanilamide was discontinued, fluids were forced, and intramuscular liver, pentnucleotide and blood transfusion were given. White blood cell counts on the succeeding five days were 400, 2,000, 2,600, 4,500 and 6,600 per cubic millimeter. The patient was desperately ill but made a complete recovery, clinical and hematologic improvement paralleling each other. Ulcerative pharyngitis was not present at any time.

CEREBRAL COMPLICATIONS

Only occasionally have patients suffered toxic psychoses of such severity that the use of the drug had to be discontinued. These have appeared either after long, continued administration or after comparatively small doses.

The following case illustrates a marked cerebral reaction due to relatively small amounts of sulfanilamide:

CASE 7.—A white girl aged 28 was admitted to the hospital because of erysipelas of the face. Sulfanilamide therapy was ordered as follows: 4 Gm. at once and 1.3 Gm. every four hours thereafter for twelve doses. A peculiar phenomenon occurred. From ten to fifteen minutes after receiving the drug the patient became so irrational, disoriented and excited as to require full restraints. Each episode lasted from two to three hours, after which the patient was again normal and had no recollection of what had happened. This occurred after each dose of the drug, so that its use had to be stopped.

HEPATITIS

Another serious complication of sulfanilamide treatment which has been encountered at Cleveland City Hospital is toxic hepatitis, five such cases having been previously reported in detail.² One case was extraordinary in that there was simultaneous occurrence of jaundice and ascites with recovery. Arsphenamine, mercurial products, phosphorus, sodium gold thiosulfate, cinchophen, common duct stone, pressure of glands on the common duct and infections are the agents which have been previously reported as being capable of so damaging the liver as to produce jaundice and ascites and yet permit recovery. Sulfanilamide can be added to this list.

SUMMARY

Symptoms of mild toxicity due to sulfanilamide such as malaise, lassitude, weakness, headache, dizziness, anorexia, nausea, slightly lowered carbon dioxide combining power and slight to moderate cyanosis or dyspnea need not cause concern.

Moderately severe symptoms of toxicity such as deep cyanosis, marked dyspnea, distinctly lowered carbon dioxide combining power, severe vomiting, diarrhea, abdominal pain, itching of the skin and slowly developing anemia indicate vigilance and possibly a reduction of dosage.

Symptoms of severe toxicity such as fever, dermatitis, acute hemolytic anemia, leukopenia, psychosis or jaundice demand immediate discontinuance of the use of the drug.

To avoid toxic manifestations one should observe the patient closely, examine the blood daily, avoid the use of sulfates and other drugs, and not use sulfanilamide in patients with anemia, leukopenia or hepatic damage.

The treatment of these toxic manifestations consists of the immediate withdrawal of the drug, bed rest, forcing of fluids, blood transfusion and such miscellaneous measures as are indicated; i. e., yellow bone marrow extract, pentnucleotide, intramuscular liver, iron, oxygen, methylene blue, sodium lactate, Ringer's solution, dextrose and insulin.

ABSTRACT OF DISCUSSION

DR. FRANCIS G. BLAKE, New Haven, Conn.: My experience with untoward reactions in sulfanilamide has been quite comparable to that described by Dr. Garvin. I have encountered two untoward reactions which he did not mention: (1) thrombopenic purpura in one case relatively mild, promptly recovering under transfusion, in another quite severe with purpura in the skin, bleeding from the kidneys and mucous membranes, the bloody pleural effusion and presumably hemorrhage about the optic nerve, causing blindness in one eye; (2) focal hemorrhage without thrombopenia. This is not rare in the retina and has been described in the literature. In addition, I have had four patients in whom severe focal hemorrhages occurred, possibly caused by sulfanilamide: in two instances gross intestinal hemorrhage, in two instances cerebral hemorrhage. In none of these four patients was there any other plausible explanation for the untoward reaction. It is particularly fortunate that Dr. Garvin stressed drug fever. It is easy to recognize drug fever when it occurs after an interval of four or five days of normal temperature, although even under these circumstances it has frequently been mistaken for a recurrence of the infection, and drug treatment resumed. Since I believe drug fever may be a warning of more serious reactions to follow, I would take the view that whenever there is a sudden rise in temperature.

2. Garvin, Curtis F.: Toxic Hepatitis Due to Sulfanilamide. J. A. M. A. 111:2283-2285 (Dec. 17) 1938.

after a period of normal temperature or a sudden exacerbation of fever, it is incumbent on the physician to establish the fact that the recurrent fever is due to infection before he resumes the use of sulfanilamide. Dr. Garvin illustrated the use of the test dose of sulfanilamide in a patient who had had a previous drug fever with scarlatiniform rash. How often do individuals who have previously had one of these untoward reactions have an accelerated untoward reaction if treated again with sulfanilamide? Information concerning this is not yet adequate, but I think experience already indicates that this is at least a fairly common phenomenon. Because of this I believe it wise to inquire whether a patient has previously had sulfanilamide and if so whether there have been untoward reactions, before using sulfanilamide for a new infection. I should like to ask Dr. Garvin whether he uses sulfanilamide in relatively mild infections. In mild streptococcal pharyngitis and tonsillitis, for example, I am hesitant about using the drug in a routine manner because of the seriousness of some of the untoward reactions.

DR. EDWIN G. BANNICK, Seattle: In view of the steadily increasing usage of sulfanilamide, Dr. Garvin's paper is well chosen, and the data he presented have much clinical value. One must constantly be on guard lest these drugs be injudiciously used. Dr. Garvin has outlined those symptoms of mild toxicity which ordinarily cause little concern, those of moderately severe toxicity which indicate vigilance and often reduction of dosage or discontinuance of the drug, and those symptoms of severe toxicity which usually demand immediate withdrawal of the drug and corrective therapy. With this grouping I heartily concur. It is important to call attention again to the latter group and to emphasize repeatedly that nearly all fatalities occurring as a result of the administration of sulfanilamide have been due to the production of either a severe hemolytic anemia, granulopenia or toxic hepatitis. The other symptoms mentioned are important chiefly because they indicate varying degrees of intolerance to the drug and therefore serve as warning signs to the physician but are of themselves not a cause of death. I believe that the severe toxic manifestations of sulfanilamide occur as a result of either idiosyncrasy or sensitivity. Those due to idiosyncrasy are usually the most dangerous and occur quite promptly and often without warning and therefore must be watched for. Every patient receiving sulfanilamide should be closely observed and should have a blood count made daily until the fact is established that he has no idiosyncrasy to the drug. Although most reactions due to idiosyncrasy are independent of dosage, nevertheless I have always preferred not to use the large initial doses advocated by some writers unless the severity of the infection demands immediate and heroic treatment, in which case, of course, it is advisable to take a chance and get an optimal concentration of sulfanilamide in the blood as soon as possible. In most cases in which the drug is used, however, it seems wiser to proceed a little more slowly and then, if there is no idiosyncrasy, the dosage can be quickly raised to the point of therapeutic effectiveness, as in cases of hemolytic streptococcus meningitis or septicemia, but not in the treatment of gonorrhea. Toxicity due to sensitivity or to prolonged administration of the drug may also be very serious, but under these circumstances there is usually some warning of intolerance, such as fever, dermatitis, jaundice or gradually developing anemia or leukopenia, and the toxicity can usually be corrected before the more serious and fatal complications have occurred. But these symptoms must be looked for and not ignored.

DR. B. K. WISEMAN, Columbus, Ohio: I think that Dr. Garvin's statement with reference to the danger of giving sulfanilamide when a leukopenia exists needs amplification. I do not consider that a reduced white cell count is necessarily a contraindication to the employment of this drug. There are, relatively, only a small number of individuals who manifest an idiosyncrasy to sulfanilamide and it is only in this group that a specific granulopenia or hemolytic anemia will develop. The initial, presenting level of white blood cells does not indicate or predispose to the fundamental tissue susceptibility which makes possible an agranulocytic syndrome. For example, undulant fever is often characterized by a leukopenia but can be

successfully treated with sulfanilamide in full therapeutic doses without adverse effect on the blood forming tissues or the development of a further granulopenia. I have used sulfanilamide without restriction as to dosage in a variety of pathologic states in which there has been an initial leukopenia and have seen no case of granulopenic syndrome develop under such circumstances. In the last analysis, the mechanism that produces the leukopenia must determine whether sulfanilamide is or is not contraindicated. If the leukopenia is the result of depression of myeloid tissue in the bone marrow or the destruction of white cells in the peripheral blood from, for example, bacterial toxins, exhibition of sulfanilamide will not further damage the bone marrow or destroy cells in the blood stream except in that small group before mentioned composed of individuals who are specifically hypersensitive to the drug. If, on the other hand, leukopenia supervenes after the administration of the drug, one should conclude in the interests of safety to the patient that the mechanism responsible for the lowering of the white count is one of specific hypersensitivity to this class of drugs, and this type of medication should be withdrawn at once. To withhold sulfanilamide purely on a criterion of leukopenia without consideration of the cause of the leukopenia is in my opinion not sound practice and may in certain circumstances be equivalent to withholding a life-saving measure.

DR. CURTIS F. GARVIN, Cleveland: Dr. Blake asked whether I believed in administering sulfanilamide in cases of streptococcal pharyngitis and streptococcal tonsillitis. I do not. I agree that the drug should not be given for relatively mild infections. I also agree with Dr. Wiseman that, although leukopenia is present, the drug can be given if a sufficient indication is present and if special care is used.

FATAL HEMOLYTIC ANEMIA FOLLOWING THE ADMINISTRATION OF SULFANILAMIDE

SIMON KOLETSKY, M.D.

CLEVELAND

Acute hemolytic anemia is now a well known complication of sulfanilamide therapy. So far only one fatality has been recorded.¹ This report describes a second fatal case.

REPORT OF CASE

Clinical History.—H. B., a Negro woman aged 64, admitted to University Hospitals Jan. 10, 1939, in the service of Dr. W. B. Chamberlin, to whom I am indebted for permission to report this case, complained of pain in the right ear. For two weeks prior to admission she had had an infection of the upper respiratory tract and sore throat with malaise and anorexia. Four days before admission pain developed in her right ear; this was followed by a thin discharge from the ear. The pain became worse and at the time of admission it was constant and throbbing.

The patient was known to have syphilis and had received antisyphilitic therapy in the outpatient department of the Lakeside Hospital from 1928 to 1930. This consisted of a total of thirty arsenical and sixty bismuth treatments. She gave a history of three miscarriages and no normal births.

Physical Examination.—The temperature was 38.5 C. (101.3 F.), pulse 100, respiratory rate 20 and blood pressure 170 systolic, 100 diastolic. The patient was well nourished and not seriously ill. There was no pallor or icterus. Except for the right ear and mastoid area there were no significant physical abnormalities. The pharynx and tonsils did not appear to be inflamed.

The right tympanic membrane was reddened and showed a perforation in the postero-inferior quadrant. A thin serous

From the Institute of Pathology, Western Reserve University School of Medicine and University Hospitals.

1. Wood, Harold: A Fatality from Acute Hemolytic Anemia Which Developed During the Administration of Sulfanilamide, *South. M. J.* 31: 646-648 (June) 1938.

exudate was present in the external auditory meatus. There was distinct tenderness over the mastoid area and pain on manipulation of the auricle.

Hospital Course.—X-ray films of the mastoids showed bilateral sclerosis of the bone and evidence of acute inflammation on the right side. On the day after admission (January 11) a right simple mastoidectomy was performed. The cortex of the bone was hard and eburnated. There was slight destruction of the walls of the mastoid air cells; many of the large cells, especially in the tip of the mastoid, contained a purulent exudate. Most of the cells were removed. Neither the lateral sinus nor the dura was exposed. The patient stood the procedure well.

The next two days (January 12 and 13) there was a slight purulent discharge from the wound and a moderate elevation of temperature. The patient's general condition was good. When the culture of the pus from the mastoid revealed pneumococcus type III it was decided to use sulfanilamide. The oral administration of the drug was started January 13 and the dosage was 1.33 Gm. every four hours. She received 1.33 Gm. on January 13, 8 Gm. on each of the next two days and 6.7 Gm. on January 16, when the drug was discontinued. The total dosage was 24 Gm. The accompanying table shows the important data in relation to the development of acute hemolytic anemia.

On admission (January 10) the red blood cell count was 3.6 million and the hemoglobin 85 per cent (Sahli). January 14,

the exterior. The inflammation involved the tympanic antrum but not the tegmen tympani or the overlying dura. There was no leptomeningitis, and the venous sinuses of the dura contained no thrombi. The left middle ear and mastoid cells, and the paranasal air sinuses of the skull showed no exudate. The brain showed no gross or microscopic lesion.

The heart weighed 350 Gm. and showed no significant gross or microscopic change. The lungs were the seat of marked hyperemia and edema, and both lower lobes showed a slight and early hypostatic bronchopneumonia.

The liver was a flabby, pale brownish red organ weighing 1,050 Gm. Microscopically the liver cells were well preserved. The Kupffer cells were large and prominent and contained much finely granular, yellowish brown pigment which was shown to contain iron by special stain. Some of the liver cells also gave a positive reaction for iron-bearing pigment.

The spleen was flabby and weighed 125 Gm. It presented a bright red bulging cut surface, and malpighian corpuscles were not readily identified. Microscopically there were hyperemia and edema of the pulp, which showed numerous large mononuclear cells filled with iron-containing pigment.

The kidneys weighed 110 Gm. each and were similar in appearance. They were the seat of arteriolar nephrosclerosis. Microscopically some of the collecting tubules contained clumps of coarse, yellowish brown material. A similar granular pigment was present within the cytoplasm of some of the cells lining these tubules. Special stain for iron was negative.

Course of Illness

Date, January, 1939.....	10	11	12	13	14	15	16	17	18
Hospital day	Admission	1 Mastoi- dectomy	2	3	4	5	6	7	8 Death
Sulfanilamide dosage, Gm.....	1.33	8	8	6.7

Hemoglobin, per cent (Sahli).....	85	65	45	38
White blood cells.....	12,500	10,250	24,300	22,200
Temperature (rectal) C.....	38.5	37.6	38.8	38	37.6	37.6	38.8	38	37.5
Treatment on sixth and seventh hospital days 5 cc. of liver extract by vein once each day									
Treatment on sixth, seventh and eighth hospital days 750 cc. of physiologic solution of sodium chloride and 750 cc. of 10 per cent dextrose intra- venously once each day									

the second day of sulfanilamide therapy, the red cells numbered 2.6 million and the hemoglobin content was 65 per cent. The next two days the patient's condition became much worse, although the mastoid wound was healing well and there was no evidence of any complication. She complained of headache and dizziness and was disoriented. There was distinct icterus of the scleras. January 16 her temperature rose to 38.8 C. (101.8 F.) and examination of the blood revealed a red blood cell count of 1.45 million, a hemoglobin of 45 per cent and a leukocyte count of 24,300. The sulfanilamide was then discontinued.

During the next two days the patient became drowsy and lethargic. January 17 the red blood cell count was 1.6 million and the hemoglobin 38 per cent. Donors for a blood transfusion could not be obtained. She was given liver extract by vein and infusions of physiologic solution of sodium chloride and dextrose. Death occurred in coma January 18, the eighth hospital day and the sixth day after the onset of sulfanilamide therapy.

Laboratory Examinations.—Urinalysis was negative. The Kline diagnostic and exclusion tests were 4+. The Wassermann reaction was negative. The icteric index (January 17) was 18. Blood smear (January 17) showed marked antisocytosis and poikilocytosis. The differential leukocyte count was 68 per cent polymorphonuclear neutrophils, 4 per cent myelocytes, 1 per cent eosinophils, 19 per cent lymphocytes and 8 per cent monocytes. Other laboratory results are given in the table.

Autopsy.—A postmortem examination was performed six hours after death. Moderate jaundice of the scleras was present and the internal organs showed marked pallor and jaundice.

There was only a slight purulent exudate at the operative site in the right mastoid, and this was adequately drained to

The sternum, ribs and vertebrae presented a homogeneous light red marrow. The entire shaft of the right femur and the middle half of the right tibia and of the right humerus were composed of yellow fatty marrow. Microscopic sections of a vertebra, of the sternum and of a rib were studied with hematoxylin and eosin and Giemsa stains and showed a similar picture. The cellularity of the marrow was within normal limits. There was distinct erythropoietic hyperplasia. The average differential of counts of 500 cells from each of the three sections was erythroblasts 17 per cent, normoblasts 25 per cent, myeloid cells (which were chiefly of myelocytic and early metamyelocytic form) 46 per cent, stem cells 12 per cent. The usual number of megakaryocytes was present.

The adrenals, pancreas and gastrointestinal tract showed no significant change.

The final pathologic diagnoses were hemolytic anemia (iron pigmentation of the liver and spleen, pallor of the viscera and generalized icterus), erythropoietic hyperplasia of the bone marrow, early hypostatic bronchopneumonia, pulmonary edema, acute suppurative mastoiditis on the right with recent surgical drainage, arteriolar nephrosclerosis, chronic salpingitis, fibromyomas of the uterus, and fibrous pleural and peritoneal adhesions.

A postmortem culture of the heart's blood showed no growth.

COMMENT

Acute hemolytic anemia is the most frequent serious complication of sulfanilamide therapy with respect to the blood. It occurs more frequently in children than in adults, and the incidence has been put at about 9 per cent of the children and 3 per cent of the adult patients

who receive the drug.² The development of the anemia is not related to the type of infection treated, the dosage of sulfanilamide or the concentration of the drug in the blood.

In every instance so far the disease has developed during the first week of sulfanilamide therapy. The hemoglobin begins to fall between twenty-four and seventy-two hours after the beginning of therapy and usually reaches its lowest level within the next three days. Thus the maximum anemia occurs most frequently on the fifth day following the onset of administration of the drug and almost always between the third and seventh days. The hemolysis of red blood cells is accompanied by an abrupt rise of the icteric index, urobilinuria and the presence of free hemoglobin in the blood. The anemia is often severe, and in the reported cases the total reduction of hemoglobin has ranged from 25 to 71 per cent.

The first fatality from an acute hemolytic anemia incident to the administration of sulfanilamide was reported by Harold Wood.¹

A Negro aged 25 with a diagnosis of hemolytic streptococcus pneumonia was given a total of 44.7 Gm. of sulfanilamide over a period of five days. The initial red blood cell count and hemoglobin content were 4.52 million and 13.5 Gm. respectively. Signs of hemolysis began two days after the onset of administration of the drug. During the next six days, although the pneumonia underwent resolution, there was a progressive anemia, and the red blood cell count fell to 1.13 million and the hemoglobin content of the blood to 3.5 Gm. per hundred cubic centimeters. A blood transfusion of 300 cc. was given on the ninth day of the disease. This was followed by slight subjective improvement, but vomiting and bleeding from the gums then developed and the patient became irrational. Death occurred four days later, on the thirteenth day after the sulfanilamide was started. Six hours before death a second transfusion of 500 cc. of blood was given.

The present patient was treated with sulfanilamide for an acute suppurative mastoiditis. This infection was evidently caused by type III pneumococcus. A total of 24 Gm. of the drug was administered over a period of four days. The hemolytic process began on the second day of therapy and progressed during the next three days. Jaundice was observed on the third day of treatment and the patient complained of headache and became disoriented. By the fifth day the red blood cell count and hemoglobin, which were 3.04 million and 85 per cent respectively on admission, had fallen to 1.6 million and 38 per cent. The patient died in coma six days after the onset of administration of the sulfanilamide. Death was attributed to the anemia and not to the infection. No blood transfusions were given because donors could not be obtained.

The pathologic changes in the present case are similar to those in Wood's case. The diagnosis of hemolytic anemia is substantiated by the diffuse pallor of all the viscera, the icterus and the demonstration of phagocytosis of iron-bearing pigment in the liver and spleen. Such changes are those of any hemolytic anemia and are in no way specific for sulfanilamide. Death was due to the anemia and to early hypostatic bronchopneumonia. Erythropoietic hyperplasia of the bone marrow was present in both cases and represents the usual secondary reaction to peripheral hemolysis of red blood

cells. This finding is of great importance because it evidently demonstrates that the bone marrow is not adversely affected by the sulfanilamide and is capable of increased hemopoietic activity.

It is of interest that both patients who died had syphilis. In the first case the Wassermann and Kline reactions were strongly positive and a syphilitic aortitis was found at autopsy. In the second case the patient gave a history of syphilis and had received fairly adequate antisyphilitic therapy about eight years prior to the present illness. On her present admission the Wassermann reaction was negative while the Kline diagnostic and exclusion tests were strongly positive. No syphilitic lesions were disclosed at autopsy. That syphilis may affect the hemopoietic system is indicated by the frequent development of secondary anemia in the florid and tertiary stages of the disease. The occurrence of these two fatalities in syphilitic patients raises the question as to whether some alteration of the hemopoietic apparatus incident to syphilis may be related to the fatal outcome.

The hemolytic anemia due to sulfanilamide results from a peripheral destruction of red blood cells. The drug either destroys these cells directly or exerts its effect indirectly, perhaps through the medium of the reticulo-endothelial system. No abnormal fragility of the red blood cells was present in the patients in whom the disease developed. The hemolysis has not been reproduced in vitro. The hemolytic reaction has been attributed to drug idiosyncrasy and the recurrence of the anemia in some cases following the resumption of sulfanilamide lends some support to this idea. The bone marrow does not appear to be directly affected by the drug and responds to the peripheral hemolysis with increased erythropoietic activity. This state of the marrow is compatible with rapid recovery of the patient once the peripheral hemolytic process caused by the sulfanilamide is terminated.

The prognosis in this complication is good. Rapid recovery follows withdrawal of the drug, forcing of fluids and blood transfusion. Transfusions should be given promptly, and repeatedly if necessary, because sulfanilamide may produce sufficient hemolysis to cause death from anemia. The immediate blood replacement provided by transfusion appears to exceed its value in stimulation of the bone marrow, especially if the red blood cell count is low. The marrow is capable of reacting to the anemia with erythropoietic hyperplasia. Another benefit of transfusion in some cases may possibly be to check the process responsible for the destruction of blood, perhaps by supplying an antihemolytic substance. This is, however, hypothetical, since the mechanism of hemolysis in this disease is not yet known.

SUMMARY

In the case here reported death was due to the anemia and to early hypostatic bronchopneumonia. The conditions found at autopsy were those of an acute hemolytic anemia, and there were no specific changes due to sulfanilamide. The bone marrow was the seat of erythropoietic hyperplasia.

In both fatal cases so far reported there was syphilis. This raises the question as to whether some alteration of the hemopoietic mechanism incident to syphilis may be related to the fatal outcome.

So far every instance of acute hemolytic anemia incident to the use of sulfanilamide has occurred during

Clinical Notes, Suggestions and New Instruments

SULFANILAMIDE IN TREATMENT OF TULAREMIA

WALKER L. CURTIS, M.D., COLLEGE PARK, GA.

March 1, 1939, a middle-aged woman suffered chills, followed by fever, nausea, vomiting and headache. When seen by me the next day she exhibited mild prostration, with a temperature of 103 F. A small ulcer was noted on the medial surface of the proximal phalanx of the right middle finger, but there was no redness or swelling of the hand or forearm; epitrochlear and axillary nodes were not palpable. As a mild epidemic of influenza was prevailing at the time, symptomatic treatment was prescribed.

Her condition grew steadily worse: to the general symptoms were added mild pain in the right arm and more severe pains over the anterolateral aspect of the chest and right upper quadrant of the abdomen; she became weaker and somewhat irrational. The afternoon temperature averaged 104.

March 14 the lesion on the middle finger had become a slightly irregular ulcer about 1.5 cm. in diameter; along its proximal border the skin could be lifted from its base. Although no evidence of lymphangitis was present, this ulcer seemed to be the only significant lesion. After blood had been secured for serologic tests, sulfanilamide was prescribed in doses of 1 Gm. (15 grains) four times a day. Because of nausea and vomiting, the drug was not taken until the 15th. March 16 her highest temperature was 102. The following day the patient telephoned that she had recovered and needed no further medical attention. The same day the State Board of Health Laboratory reported that the test for tularemia was positive in a dilution of 1:320 but that tests for typhoid, paratyphoid, Brill's disease, brucellosis and syphilis were negative. The highest temperature on the 17th was 98.8 and she has been well ever since. Sulfanilamide was continued however until she had taken 14 Gm. (210 grains).

On the thirty-ninth day after the beginning of the illness, a gland was noted in the right axilla which increased in size till it was 3 cm. in diameter five days later. Since then there has been no change in the size of the gland.

April 30 the agglutination test for tularemia was positive in a dilution of 1:5,120.

After the patient had recovered she recalled that a week before she became ill she had taken some dressed rabbits from salt water and wrapped them up. The nature of her occupation was such that she often had scratches and abrasions of her hands.

COMMENT

Tularemia has been recognized as endemic in Georgia for a number of years. In this case there was no history of a previous illness simulating tularemia. It was learned that the patient had handled dressed rabbits about eight days before the onset of the acute illness. The agglutination test, positive in a dilution of 1:320 in the third week, became positive in a dilution of 1:5,120 in the ninth.

Adenopathy occasionally does not appear in the ulceroglandular type of tularemia until after the acute symptoms of the disease have subsided. Distribution of pain similar to that described in this case has also been reported occasionally.

Two days after the administration of sulfanilamide the symptoms of tularemia, severe for over two weeks, subsided and convalescence has been uneventful. So far I have found no report of an earlier case of tularemia successfully treated with sulfanilamide.

The patient was presented before the Fulton County Medical Society, May 4, 1939.

STANDARD METHOD FOR TAKING AND RECORDING BLOOD PRESSURE READINGS

BY THE COMMITTEE FOR THE STANDARDIZATION OF BLOOD PRESSURE READINGS OF THE AMERICAN HEART ASSOCIATION

DRS. M. H. BARKER, CHICAGO; JOSEPH ERLANGER, ST. LOUIS; JONATHAN MEAKINS, MONTREAL; RALPH SCHNEIDER, NEW YORK; S. B. SCHOLZ JR., PHILADELPHIA; HARRY UNGERLEIDER, NEW YORK; PAUL D. WHITE, BOSTON; CARL WIGGERS, CLEVELAND, AND IRVING WRIGHT, NEW YORK, CHAIRMAN

AND THE

COMMITTEE FOR THE STANDARDIZATION OF BLOOD PRESSURE READINGS OF THE CARDIAC SOCIETY OF GREAT BRITAIN AND IRELAND

DRS. CRIGHTON BRAMWELL, MANCHESTER, ENGLAND; T. F. COTTON, LONDON; WILLIAM EVANS, LONDON; A. R. GILCHRIST, EDINBURGH, SCOTLAND; JOHN HAY, LIVERPOOL, ENGLAND, AND MAURICE CAMPBELL, LONDON, CHAIRMAN

It has long been realized by thoughtful teachers and practitioners of medicine that the wide variations noted in blood pressure¹ records of the same individual were due not only to changes in the pressure from time to time under different conditions but also to differences in the methods and interpretation used by the observers. A recent survey² revealed a serious lack of agreement among physicians as to the correct technic for taking and interpreting the blood pressure. Equally confusing was the situation among insurance companies as to what they should require of their examiners in this regard. Experiments with multiaural stethoscopes demonstrated that recent years have brought little if any improvement in this situation, since the variations among the recently qualified were as great as those among attending physicians, and the range of error was too great among all groups tested. The committees for the standardization of methods of blood pressure readings appointed by the American Heart Association and by the Cardiac Society of Great Britain and Ireland have attempted to secure a crystallization of the best available thought on this subject.

The joint committees were asked if feasible to make recommendations which might be accepted as constituting standards for practicing physicians, medical teachers, insurance carriers and all others interested in this problem. After a careful study of material available from many sources, the committees of the American Heart Association and of the Cardiac Society of Great Britain and Ireland jointly recommend the following procedure as the standard method for taking and recording blood pressure readings in man:

STANDARDIZATION OF BLOOD PRESSURE DETERMINATIONS

1. *Blood Pressure Equipment.*—The blood pressure equipment to be used, whether mercurial or aneroid, should be in good condition and calibrated at yearly

The recommendations contained in this report have been approved by the Association of Life Insurance Medical Directors of America.

1. "Blood pressure" by common usage signifies arterial pressure and for that reason is so used throughout this report.

2. Wright, I. S.; Schneider, R. F., and Ungerleider, H.: Factors of Error in Blood Pressure Readings, *Am. Heart J.* 16:469-476 (Oct.) 1938.

intervals for accuracy, and more often if defects are suspected (mercurial preferred by British committee).

2. *The Patient.*—The patient should be comfortably seated (or lying—British committee) with the arms slightly flexed and the whole forearm supported at the heart level on a smooth surface. If readings are taken in any other position, a notation should be made. The patient should be allowed time to recover from any recent exercise or excitement. There should be no constriction of the arm due to clothes or other objects.

3. *Position and Method of Application of the Cuff.*—A standard sized cuff containing a rubber bag from 12 to 13 cm. in width should be used. A completely deflated cuff should be applied snugly and evenly around the arm with the lower edge about 1 inch above the antecubital space and with the rubber bag applied over the inner aspect of the arm. The cuff should be of such a type and applied in such a manner that inflation causes neither bulging nor displacement.

4. *Significance of Palpatory and Auscultatory Levels.*—In all cases palpation should be used as a check on auscultatory readings. The pressure in the cuff should be quickly increased in steps of 10 mm. of mercury until the radial pulse ceases and then allowed to fall rapidly. If the radial pulse is felt at a higher level than that at which the auscultatory sound is heard, the palpatory reading should be accepted as the systolic pressure; otherwise the auscultatory reading should be accepted.

5. *Position and Method of Application of Stethoscope.*—The stethoscope should be placed over the previously palpated brachial artery in the antecubital space, not in contact with the cuff. No opening should exist between the lip of the stethoscope and the skin; this should be accomplished with the minimum pressure possible. The hand may be pronated or supinated according to the position yielding the clearest brachial pulse sounds.

6. *Determination of the Systolic Pressure.*—The cuff should be rapidly inflated to a pressure about 30 mm. above the level at which the radial pulse can be palpated. The cuff should then be deflated at a rate of from 2 to 3 mm. of mercury per second. The level at which the first sound regularly appears should be considered the systolic pressure unless, as already described, the palpatory level is higher, in which event the palpatory level should be accepted. This should be noted.

7. *Determination of the Diastolic Pressure and the Pulse Pressure.*—With continued deflation of the cuff, the point at which the sounds suddenly become dull and muffled should be known as the diastolic pressure. If there is a difference between that point and the level at which the sounds completely disappear, the American committee recommends that the latter reading should be regarded also as the diastolic pressure. This should then be recorded in the following form: RT (or LT) 140/80-70 or 140/70-0. If these two levels are identical, the blood pressure should be recorded as follows: 140/70-70. The cuff should be completely deflated before any further determinations are made.

The British committee believes that except in aortic regurgitation it is nearly always possible to decide the point at which the change comes and this is the only reading that should be recorded.

EXPLANATORY COMMENTS

In addition to these specific recommendations, the committee believes that certain other factors should be taken into consideration by the physician who makes blood pressure determinations.

The relative merits of various types of blood pressure apparatus have been the subject of numerous reports. In the opinion of the joint committees, mercurial and aneroid types of apparatus are capable of correct readings if they are in good condition, and both types of equipment may produce inaccurate results if not in good condition. This factor is often overlooked in the case of the mercury manometer, which should be checked at intervals as to the following points:

1. The level of the mercury at rest should be exactly at the zero mark. If some of the mercury has leaked out, this will not be the case. The missing mercury should be replaced.

2. If the small air vent at the top of the glass tubing becomes clogged, a definite lag may be produced; the mercury column may not register the pressure in the bag, and the readings will therefore be incorrect.

3. The apparatus must be on a level surface, since tilting of the manometer will result in incorrect readings. It should also be level with the observer's eyes.

A yearly calibration of the aneroid type of instrument against a U-tube standard is recommended. This is particularly advisable for the older instruments, in which a sharp blow or fall may cause inaccuracies as the result of changes in the aneroid diaphragm. The needle should stand at zero when the apparatus is completely deflated and move immediately when the inflation begins. Manometers which have a stop pin at zero or which have a rotatable dial permitting the user to set the zero mark anywhere are not recommended, since a satisfactory check with these types of instrument is impossible.

In both types of equipment the valves of the instrument, including those of the rubber bulb, should be competent and function smoothly. The entire system, including the "pressure" rubber tubing and rubber bag, must be free from leakage and be kept in good condition. It is recommended that the instrument to be used be checked at yearly intervals against a machine known to be in perfect condition. More frequent checks should be made if the accuracy of the instrument is in doubt. The rubber cuffs used should be from 12 to 13 cm. wide and 23 cm. long. The cloth covering should be of inextensible material of such a nature that even pressure is exerted throughout the width of the cuff; it should extend as a band 15 cm. wide for 60 cm. beyond the edge of the rubber cuff and then taper gradually during an additional 30 cm. New types of cuff using a slide fastening device or hooks on a rib extending the width of the cuff appear to be more satisfactory than the long tapering cuff end. If bulging occurs above and below the band, the reading may not be accurate.

A special cuff should be used to record blood pressures of the leg. The rubber bag should be 15 cm. wide and its covering 17 cm. wide, and 30 cm. longer than in the case of the armlet (total 120 cm.). For children, cuffs of the following widths have been suggested: under 8 years, less than 9 cm.; under 4 years, less than 6 cm.; newborn, less than 2.5 cm. The limited work done in this field does not warrant a definite recommendation at this time.

The American committee selected the sitting position as the preferred choice because of the fact that it simplifies the taking of large numbers of blood pressure readings. It is true that many patients are bedridden but in most instances they can be propped up into a sitting position without causing more than transitory

disturbances in the circulation; and when this is impossible it is suggested that a notation be made as to the position in which the blood pressure is taken. The British committee did not think that there was any significant difference between the sitting and lying positions. For blood pressure readings of the thighs, the auscultation should be over the popliteal artery with the patient prone.

Certain physical and psychologic factors should be considered. Inquiry should be made as to the patient's activity just before the examination. Exercise and meals affect the blood pressure. A rest period of from ten to fifteen minutes prior to the making of the observations will eliminate or minimize certain of these factors. It is important that the physician evaluate the degree of stress or emotional crises through which the patient is passing. The first reading taken by a physician is often much higher than later ones, owing to apprehension and nervousness on the part of the patient. It is often wise, therefore, to avoid conclusions regarding the blood pressure level of an individual until several readings have been made on successive visits. This is especially important with hypertensive and hyperthyroid patients. Any evidence of apprehension or of undue concern on the part of the physician may alarm the patient and increase the pressure.

There are variations in the blood pressure level of certain individuals in the course of a day. It is therefore suggested that for careful records the time of the day should be noted, and if the patient is being carefully followed in reference to the blood pressure level the observations should be made at essentially the same time and in the same relationship to meals, sleep, exercise and other similar factors.

The term "points" is suggested for use in reference to diastolic pressure, since the former commonly used word "phase" implies a measure of time interval, whereas in reality the fourth and fifth "points" are the exact levels at which change is made from one phase to the next. Detailed discussion in reference to the second and third phases is not pertinent to this report, since those phases are of little if any practical importance and tend to confuse the issue at hand. It should be clearly recognized that a single figure for systolic or diastolic pressure apparently does not represent actual pressure within from 5 to 10 mm. of mercury. If the physician wishes to minimize the sources of error several blood pressure readings should be made, the highest and lowest pressures during the course of this series being recorded. Whereas an average of the series of readings might be recorded, this would not have the same significance in instances of cardiac irregularity.

The determination of blood pressure in arrhythmias is unsatisfactory at best when made with the apparatus under discussion. With premature beats the higher systolic pressure of the beats that terminate compensatory pauses should be ignored. With auricular fibrillation both diastolic and systolic readings should be recorded as approximate only. It is suggested that in this condition the average of a series of readings for the reappearance of sound be noted as the systolic pressure and that similar averages for the fourth and fifth "points" be recorded as the diastolic pressure. The diagnosis, if not stated elsewhere on the patient's chart, should be noted with the blood pressure recording. In aortic regurgitation with a collapsing pulse the diastolic end point is sometimes marked by a less obvious change

in the quality of the sounds than normally. This change may be difficult to appreciate.

Alternation of the pulse during blood pressure determinations may indicate left ventricular weakness.

It is suggested that, when especially careful studies of the blood pressure are to be made, the use of basal blood pressure conditions should be considered. A preparation similar to that used in making a basal metabolism test is recommended. Such a basal blood pressure determination should be made from ten to twelve hours after a previous meal (preferably in the morning) after the patient has rested for thirty minutes in a comfortably warmed room. The patient should be mentally as well as physically at ease. This procedure would be most useful in experimental studies when an accurate standard level is desired. Objections to its use in general practice are obvious.

When auscultatory methods alone are used, the actual blood pressure level may be definitely higher than the level at which the first sounds are detected. Under the circumstances the palpatory reading will be the more correct of the two. If both palpatory and auscultatory methods are used as recommended, this error will be detected.

In occasional instances the usual sounds are heard over the brachial artery at a fairly high level; as the pressure in the cuff is reduced, the sounds completely disappear only to reappear at a distinctly lower level. This zone of silence is known as the auscultatory gap. Its existence is obviously important, as it is possible in such cases to inflate the cuff only to the level of the auscultatory gap and to record the systolic pressure at the level where sounds are first heard, which may actually be 40 or 50 mm. below the true systolic level.

The importance of avoiding unnecessary venous congestion should be recognized. This can be minimized by making certain that there are no constricting bands on the patient's arm and that the pressure cuff is not kept inflated longer than absolutely necessary to make the blood pressure reading. Decompression should be at the rate of approximately 2 to 3 mm. of mercury per second. After a reading has been made, the cuff pressure should be reduced to zero long enough to allow the veins to empty before another determination is started.

It is suggested that on the first examination of the patient the blood pressure in both arms be taken, since the two may not be the same. If the patient is followed for a period of time this procedure might wisely be repeated at stated intervals of every few months and at other times if indicated by developments. In the presence of unexplained high pressure in the brachial artery, it is suggested that blood pressure in the legs be taken also. By this procedure conditions such as coarctation of the aorta may be detected.

If the variations in blood pressure which occur with respiration are considerable, this factor may be eliminated by taking a reading while the patient holds his breath at midrespiration, but this must be for only a short interval or abnormal blood pressure readings will result because of asphyxia and other factors.

Certain factors inherent in the physician, such as variations in accuracy of hearing, must be recognized as important. A physician who is aware that his hearing has become impaired should use a stethoscope which is amplified to a greater extent, and in the event of marked deafness electrically amplified or other mechanical devices should be utilized. It is thought inadvisable

at this time to make recommendations regarding automatically recording blood pressure equipment.

The combined use of the auscultatory and palpatory methods as described herein will yield routine data that are as reliable as those given by any other method. Under exceptional circumstances, as when the pulse is too feeble to produce sounds or too irregular for averaging, recording methods may become necessary. Those contemplating the use of graphic methods should first ascertain through reliable sources whether they will subserve the ends in mind.

The recommendation of a standard procedure as outlined by the committee is not intended to discourage initiative when indicated in special situations.

CONFERENCES ON THERAPY

VITAMINS; VITAMIN B₂ THERAPY

NOTE.—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors.

DR. McKEEN CATTELL: We have for our topic this morning vitamin therapy with special reference to vitamin B₂. Dr. Rhoads, from the Rockefeller Institute, has kindly come over to lead the discussion.

DR. C. P. RHOADS: Last year when the therapeutic use of vitamins was discussed before this group it became clear that so broad a topic could not be presented adequately in a single conference. It has seemed wise, therefore, to limit this discussion to a single phase of the problem and to consider only those effects of the deficiency of vitamin B₂ (the heat-stable, water-soluble B complex) which are concerned with pernicious anemia, sprue and pellagra.

As a matter of historical interest it should be recalled that our first definite information concerning the vitamin B complex came from the work of Takaki, a Japanese naval surgeon, who made the significant observation that beriberi was particularly common among those whose diets were composed almost entirely of polished rice. From this observation the concept of beriberi as a deficiency disease developed, and when the deficient rice diets were supplemented with meats and vegetables the disorder almost disappeared. The later study of Eijkman was based on this original work and proved that the antiberiberi substance is present in grain germs and hulls. It was learned, furthermore, that the vitamin is destroyed rather quickly by heat. We now know, thanks to the work of Williams, that this heat-labile antineuritic, beriberi preventing vitamin, formerly called B₁, is a chemical compound known as thiamin. We know further that it is active after phosphorylation, as the prosthetic group of a coenzyme carboxylase, which has to do with carbohydrate metabolism.

The next step concerning vitamin B was the observation by Goldberger that something contained in yeast, meat, milk and certain vegetables would prevent and cure pellagra. Goldberger established the facts that his antipellagra material had roughly the same distribution in nature as the antiberiberi vitamin but differed from that substance in being stable to heat. Accordingly, the pellagra preventing material was a second constituent of the water-soluble vitamin B com-

plex and as such was termed vitamin B₂. Since Goldberger's original study, we have learned that his effective material is the amide of nicotinic acid and is active, after phosphorylation, as the prosthetic group of a coenzyme, which has to do with carbohydrate metabolism. At least two other constituents of the B₂ complex have been identified—one a flavin complex and the other a substance known as vitamin B₆; further studies will prove it is hoped, the exact action of these constituents. There may be still more which have not been identified.

The recent chemical isolations of pure vitamins have obscured the important original observations of those who worked with crude substances. It should be recalled that Goldberger discovered the cure of pellagra, although he worked under the greatest difficulties. Any one interested in the vitamin B₂ complex should read Goldberger's original papers, since they are classic examples of productive investigation. He established the fact that inadequate diets were eaten uniformly by human beings who contracted pellagra, and he demonstrated the curative value of more liberal diets. By feeding to animals the diets which were eaten by pellagrins he then produced an experimental disease like pellagra and cured it by the same dietary constituents which cured the human subjects. Finally, he made the crucial experiment of producing pellagra experimentally by feeding to human volunteers deficient diets like those which caused symptoms in experimental animals.

STUDIES ON SPRUE AND PERNICIOUS ANEMIA

The next advance in the study of heat-stable vitamin B₂ complex was the discovery of the cure of pernicious anemia. The curative effect of liver feeding in that disease was proved by Minot and Murphy following the suggestion of Whipple. It is interesting to note that, before Minot's paper appeared, Gibson and Howard described remissions in cases of pernicious anemia after eating diets rich in liver. Lacking precise methods for evaluating the effect of specific therapy, they did not realize the importance of their observation, however. Minot had developed such a precise method in the reticulocyte curve, and its use probably contributed greatly to the discovery.

You may ask what the liver treatment of pernicious anemia has to do with the vitamin B complex. The relationship became apparent from the studies of Castle, who observed that a dietary constituent allied to that complex interacted with a factor present in normal gastric juice to form a third substance which is present in liver and is curative of pernicious anemia. The observation developed as follows: Castle knew that achlorhydria was a constant feature of the gastric juice of patients with pernicious anemia. He knew that the disease could not be cured by the administration of any known constituent of gastric juice—pepsin, rennin or hydrochloric acid—and he was convinced that the constancy of achlorhydria in pernicious anemia was concerned with the etiology of the disease. He had the determination to prove that his conviction was valid. It had been noticed that the diets of many patients with pernicious anemia were low in their content of meat. Accordingly, Castle ate beef muscle, allowed it to digest in his own stomach, removed it, neutralized it, and fed the mixture to patients with pernicious anemia. They were regularly cured. He continued the study to prove that beef muscle alone was inactive, and that gastric juice alone was inactive, but that when the two were incubated together something was formed which

was curative. Although the product of the interaction is not the same substance which can be extracted from liver, it must be very closely akin to it, since the two have the same physiologic effect. Castle coined the terms "extrinsic factor" for the substance present in beef muscle and "intrinsic factor" for the substance present in normal gastric juice and absent from the gastric juice of patients with pernicious anemia.

At the time of the original experiment, Castle had no reason to believe that the active constituent of beef muscle was a vitamin. The knowledge that this substance was allied to the heat-stable vitamin B₁₂ complex developed later, partly from the work of Wills and partly from the studies of sprue made by Castle and by me.

In 1931 Wills described a macrocytic anemia which occurred in malnourished women in Bombay. Hematologically this disorder was similar in many respects to pernicious anemia but it could be cured by feeding a concentrate of autolyzed yeast without added normal gastric juice. It could also be cured by liver extract. From the Castle mechanism of extrinsic factor interacting with gastric factor to allow the formation of a liver factor, it was clear that the absence of any one of these three should result in pernicious anemia, curable either by liver extract (as the end product) or by supplying the missing factor. The observation of Lucy Wills suggested that she was dealing with pernicious anemia due to a lack of dietary factor, although she had cured her patients with yeast rather than with beef muscle. If the disorder were like pernicious anemia the observation was evidence that the same or a similar substance was present in the yeast which Wills administered, as in the beef muscle which Castle employed as extrinsic factor.

In further support of the Castle hypothesis of a tripartite etiologic mechanism of pernicious anemia was the fact that a number of cases of that disorder had occurred following gastrectomy. Presumably the intrinsic, or gastric, factor had been surgically removed in these cases. Finally, as an example of pernicious anemia due to lack of hepatic factor was the macrocytic anemia associated with certain forms of liver disease. Although this anemia does not respond very well to treatment effective in pernicious anemia, this fact can be explained in such a way that the Castle hypothesis is not invalidated.

Suggestive of the existence of dietary pernicious anemia as the evidence just mentioned seems to be, further proof was required. This proof was obtained in part from studies made by the second Rockefeller Foundation Commission for the study of anemia in the tropics. This commission was under the direction of Dr. Castle, and I had the great privilege of taking part in its activities. We were confronted with the problem of ascertaining the cause and, if possible, the cure of tropical sprue. It was known that sprue was characterized by stomatitis, glossitis, macrocytic anemia and gastrointestinal disturbance. These symptoms are similar qualitatively to the symptoms of pernicious anemia though they differ quantitatively. Clinical study established the fact that sprue and pernicious anemia were more similar than we had supposed them to be, although certain differences existed. The most striking likeness was in the anemia, since in many instances it seemed to be of exactly the same type as that of pernicious anemia. It seemed possible that sprue anemia was pernicious anemia, not arising from lack of the gastric intrinsic factor of Castle, as was the case in the per-

nicious anemia of temperate zones, but from a lack of some other part of the Castle tripartite mechanism. The possibility was investigated that lack of the dietary factor was at fault, and definite histories of dietary insufficiency in substances known to be rich in the extrinsic factor of Castle were established in many instances. The gastric intrinsic factor was also investigated. In contrast to pernicious anemia of temperate zones, a majority of the patients with pernicious anemia of sprue were able to secrete hydrochloric acid in their gastric juice. It was clear that for an understanding of sprue the original Castle experiment would have to be repeated on patients with that disorder. This repetition would establish whether the anemia of sprue was due to a lack of dietary, gastric, or hepatic antipernicious anemia factor.

A series of cases of sprue with macrocytic anemia of severe degree were tested by feeding in a first period beef muscle, in a second period beef muscle and gastric juice, and in a third period liver extract. In a fourth period liver extract was injected. If the patients responded by increased reticulocytes to the feeding of beef muscle, it was clear that the anemia was due to a previous lack of some constituent of beef muscle. If there was no response to the feeding of beef muscle but a response did follow the feeding of a digest of beef muscle and normal gastric juice, it was proof that gastric, or intrinsic, factor was lacking, as was the case in classic pernicious anemia. If no response followed either of these two experiments but did occur after the feeding of liver extract, it was evidence of some interference with the conversion into liver extract of the product of the interaction of extrinsic and intrinsic factors. Finally, if no response occurred in any one of the first three periods but did occur after the injection of liver extract, two explanations were possible: either the absorption of antianemia factor from the intestinal tract was interfered with or an excessively large amount of this factor was required.

In the series studied in the manner just outlined, examples of all four possibilities were encountered. Some patients responded to the feeding of beef muscle alone, and these patients tended to have free hydrochloric acid in the gastric juice. Other patients responded not at all to beef muscle but only after the beef muscle had been digested with normal gastric juice. These cases were physiologically analogous to classic pernicious anemia. A third group showed responses to liver extract given by mouth and it was concluded that some interference with the production of liver extract factor from extrinsic and intrinsic factor was at hand. Finally, certain patients gave a response to injected but not to orally administered liver extract, a fact which suggested that absorption of anti-anemic principle from the intestine was interfered with. In brief, in this series, examples of pernicious anemia due to a lack of any one or all three of the constituents of the Castle mechanism were observed.

In the next experiment a similar study was made in which autolyzed yeast was substituted for beef muscle as a source of dietary factor. This was done to establish the fact that the same effective substance was present in the autolyzed yeast fed by Wills as in the beef muscle fed by Castle. The results were in general parallel to those which have been described, and accordingly the evidence was clear that yeast could serve in the place of beef muscle as a source of dietary or extrinsic factor. Furthermore, it could be shown that the active principle in the yeast was stable to heat,

suggesting that it was a part of the vitamin B₁₂ complex. The evidence was strong that sprue anemia was basically pernicious anemia but that many cases were caused by a somewhat different defect than the gastric one which caused pernicious anemia of temperate zones.

As further proof it was possible to test for anti-pernicious anemia potency the liver of a patient dying by accident with a severe macrocytic anemia of sprue. When a suitably prepared extract of this patient's liver was injected into a patient with pernicious anemia no response was obtained but, when the same patient was tested by injecting a similarly prepared extract of normal human liver, remission was effected. Clearly the case of sprue anemia was due to the same lack of a substance contained in the patient's liver as caused the hematologic disorder of pernicious anemia.

Finally, the gastric juice of patients with sprue was incubated with beef muscle and tested directly on patients with pernicious anemia. You will recall that if the gastric juice of a patient with pernicious anemia is digested with beef muscle and fed to another patient with pernicious anemia no effect is obtained. If, for the pernicious anemia gastric juice, the gastric secretion of a normal individual is substituted, cure follows. In two tests of the gastric juice of patients with sprue there was no effect on the patient with pernicious anemia, but remission was obtained when normal gastric juice was substituted for the gastric juice from the patient with sprue. It appears that these two patients had anemia and presumably the other symptoms of sprue for exactly the same reason that people have pernicious anemia: they lacked gastric intrinsic factor. In a third test, however, a different result was obtained. Here the sprue gastric juice digested with beef muscle and fed to a patient with pernicious anemia gave a response as good as that which could be expected from the administration of normal gastric juice-beef muscle digest. It was apparent that this patient with sprue did not have anemia because he lacked gastric factor but only because dietary factor was wanting. It was, in other words, a dietary rather than a gastric pernicious anemia.

The clinical experiments seemed to be clearcut. It was next necessary to produce in animals a disorder something like sprue or pernicious anemia in human beings. It was necessary, furthermore, to be able to cure this disorder by the substance, liver extract, which cured sprue and pernicious anemia in man. Goldberger had produced the analogue of pellagra in dogs by feeding diets which lacked a factor contained in yeast and now known to be in part nicotinic acid. The symptoms in Goldberger's dogs, stomatitis, glossitis and diarrhea, were not only features of pellagra but also features of sprue and pernicious anemia. Whereas pellagra was clearly a disorder distinct from sprue and pernicious anemia, it might be that by some modification of the diet in experimental animals a disease could be produced which would be less like pellagra and more like sprue, with an anemia similar to that of sprue and pernicious anemia.

By feeding to dogs a modification of Goldberger's diet, anemia, stomatitis and diarrhea could be made to occur and could be cured by supplementing the diet with liver extract. The results were inconsistent and the experiment useful only as a guide. The fact then developed that the dog possessed little gastric or hepatic factor effective against pernicious anemia in man. The dog apparently used some constituent of yeast directly without conversion by gastric secretion or liver. It

was known, however, that the pig did possess anti-pernicious anemia factor in his stomach since ventriculin, an effective therapeutic agent in pernicious anemia, was made from pig's stomach. Accordingly the modified pellagra-producing diet of Goldberger was fed to young pigs. The animals failed to grow, developed achlorhydria, evidence of neurologic involvement, stomatitis, diarrhea and anemia. These symptoms could be prevented and cured by administering liver extract. They could also be prevented by supplementing the diet with heated yeast, the same material which was effective as a source of dietary factor in the anemia of sprue and pernicious anemia. The anemia was inconstant in the swine, occurring in about 40 per cent of the animals studied. When it occurred, hyperplastic, immature bone marrow was present, not unlike that seen in sprue and pernicious anemia in human beings. When the gastric juice of the achlorhydria swine was incubated with a source of dietary factor and fed to patients with pernicious anemia, no response was obtained but was effected when normal swine gastric juice was employed. Finally, liver extract was made from the livers of improperly fed achlorhydric and anemic swine and injected into patients with pernicious anemia. There was no effect. A response was obtained, however, when normal swine liver, similarly extracted, was used. It seemed clear that by feeding to swine a diet lacking in some heat-stable constituent of yeast the animal's liver was unable to store a factor which would prevent or cure pernicious anemia in man. This experiment was of some importance because it indicated that bad diets could in turn cause improper gastric function and the combination could result in a decreased content of the liver in anti-pernicious anemia factor.

As knowledge has developed in the last two years, these experiments are wanting in certain specific information. We know that nicotinic acid is part of the active constituent of heated yeast which is curative of pellagra. Nicotinic acid seems to have no curative effect in either pernicious anemia or sprue. The diets fed to the animals were empirically devised to produce the desired symptoms. We did not know, and do not know now, what factor or factors were lacking in them. Very slight changes in the composition of diets designed to be deficient in certain specific constituents may result in quite different symptoms. More extensive investigation of this subject is required.

Further study of sprue revealed an interesting and unexpected fact. Many cases required enormously greater amounts of antianemic liver extract than did patients with pernicious anemia at the same blood levels. This fact suggested that in sprue, as well as in some cases of pernicious anemia, some factor might be operative which increased the requirement for antianemic material—in other words, some metabolic abnormality of the body might condition the deficiency of liver extract (the product of the interaction of gastric juice and the vitamin B₁₂ complex). It was known that patients with pernicious anemia excreted large amounts of indican as ethereal sulfate in the urine. Accordingly, the effect of feeding indole, the source of indican, to dogs was tried. There was little or no effect on the blood picture. If, however, these dogs were fed diets lacking in the B₁₂ complex but insufficiently so to cause anemia, the administration of indole produced a severe hemolytic disorder with exceedingly low blood levels and without essentially elevated levels of reticulocytes. If the administration of indole was continued and the diets were supplemented with liver extract as a source

of the lacking factor, reticulocyte crises and rapid disappearance of the anemia resulted. This effect was coincidental with a decrease in the activity of the hemolytic process. This experiment is of some importance. It demonstrates for the first time that the toxicity of a compound may be conditioned by the lack of a dietary constituent. Further evidence of this principle is accumulating rapidly from different laboratories. I need only quote the experiments concerning the increased toxicity of naphthalene when animals are fed diets lacking cysteine, and the studies of White concerning a similar modification of the toxic effect of methylcholanthrene. The balance between the toxic compound and the dietary constituent is remarkably constant. If an excessive dose of the toxin is given, indole in our experiments, anemia will develop irrespective of the amount of vitamin fed. If a small amount of toxin is given and a normal diet fed the anemia disappears. If the same dose of toxin is continued and the diet is made deficient the anemia reappears. Even though the administration of toxin is continued, however, the anemia disappears once more when the lacking factor in the diet is administered.

Since the original studies of sprue and of pernicious anemia, certain new clinical observations have been made. It appears that the various manifestations of the full blown disorders may occur separately, without the usual concomitant symptoms. If properly recognized as evidence of deficiency disease, these isolated symptoms may be treated quite as effectively as the complete syndrome. For example, pellagrous-like stomatitis may occur without the other signs of pellagra and respond to antipellagra treatment. Central nervous system disorders like that of the combined system disease usually seen in pernicious anemia may occur without anemia. Treatment with liver extract seems to be effective in these cases.

The fundamental contributions of the biochemists have clarified to some extent the precise actions of certain components of the vitamin B₂ complex. Of these components two have been identified, nicotinic acid and flavin. Both are active in enzymes after phosphorylation and combination with specific proteins. The enzymes are required for the proper oxidation and reduction processes of the body. In oxidation, hydrogen leaves the substrate and is taken up by cozymase (the nicotinic acid enzyme), which is itself reduced. In turn the hydrogen is given up by the coenzyme with its reoxidation and taken up by the flavin coenzyme with its reduction. Finally the hydrogen is transferred to a third enzyme and the flavin compound becomes oxidized once more. From these facts it is apparent that without these hydrogen carrying vitamin-enzymes the most fundamental processes of the body cannot proceed. It is not surprising that deficiency disease results in striking symptoms.

The last point to be considered is how deficiency disease can occur in the presence of an adequate intake of the essential dietary constituents. Simple deficiencies which occur because of poor diets are easy to understand. A mass of evidence has accumulated, however, which proves that symptoms of vitamin lack may occur in other ways. Vitamins may be washed out of the intestinal tract by diarrhea before they can be absorbed. They may fail to be absorbed even though diarrhea is not a marked feature. They may fail to be converted to a usable form, as is the case in pernicious anemia. Infection may inhibit the action of vitamins by some

toxic action. Finally, the work of Brown advances clear evidence that individuals vary greatly in their requirement for dietary constituents: a good foundation for the statement "One man's meat is another man's poison." If these principles are borne in mind the treatment of symptoms of deficiency disease becomes one of the most fascinating and satisfactory duties of clinical medicine.

DISCUSSION

DR. CATTELL: We now have a period for questions and discussion. There must be a number of points which can be presented for further discussion.

DR. HARRY GOLD: Would Dr. Rhoads say whether there are any clinical states of ill health other than pellagra, sprue and pernicious anemia in which the vitamin B₂ complex is useful?

DR. RHOADS: You refer to any constituent of the B₂ complex?

DR. GOLD: The mixture.

DR. RHOADS: That depends a great deal on how you define pellagra, sprue and pernicious anemia. We see constantly in our hospital on the infectious service a disorder marked by stomatitis and often by mild neurologic disturbance. It may occur with or without achlorhydria or a diminution of free hydrochloric acid. In treating this disorder the B₂ complex is exceedingly useful. We see a good many cases of mild nervous system disorder which clinically is not dissimilar from combined system disease but is associated with rather little blood changes and not always with achlorhydria. We think that liver extract is very useful in treating this condition.

We are also interested in a large group of individuals with various disorders of the oral mucous membrane, most of them without much anemia. Much can be done with B₂ complex to maintain the integrity of those mucous membranes.

DR. GOLD: Are there any skin manifestations other than the classic lesions of pellagra which respond to vitamin B₂ complex?

DR. RHOADS: That is very hard to answer. You probably know that we have been working with several dermatologists here in town for a considerable period in an attempt to pick out a group of skin disorders which will respond. Such a group seems to exist. At the present stage of the work it is not possible to pick out cases which will respond regularly. Much more experience is required.

DR. E. F. DU BOIS: Dr. Rhoads, I was particularly interested in what you said about the evidence of vitamin deficiency in the patients with pneumonia. A good many years ago I had the privilege of working with Dr. Warren Coleman, studying the diet in typhoid fever, in the period before we realized the importance of the vitamins. I am wondering how much of the improvement in the typhoid fever patients was due to the increase in vitamins in the diet and how much was due to the mere caloric content.

DR. RHOADS: That is an exceedingly interesting point. As a matter of fact, you made this suggestion a year or two ago. The suggestion led Dr. MacLeod to watch the pneumonia patients more carefully. As soon as we did so it was apparent that many of our patients severely ill with pneumonia were getting a marked atrophic glossitis along in the first five or six days of convalescence. It apparently responds very dramatically to the administration of the B complex in heavy

dosages, either as yeast or as liver extract. The mechanism is very interesting in that if you watch these people most carefully day by day the disorder is seen to begin as the old fashioned coated or furred tongue. We think that the coating represents simply the beginning of necrosis of the papillae. As the condition progresses the whole surface suddenly peels off in a few hours leaving the typical slick, red, atrophic surface of the pellagrous tongue. As treatment is given the papillae grow again and the normal surface is restored.

DR. DU BOIS: As I remember, back about twenty-six years ago the thing that struck us most in the improvement of the typhoid patients, one of the things that was manifested first, was the improvement in the condition of the mouth. We thought that was due to better nursing, to care of the nose, so that it wasn't stopped up, causing the patients to breathe through their mouths, or because of their improved mental condition. But the tongues improved so rapidly that in the latter stages of the typhoid fever, along about the second week of the disease, the tongues of the typhoid patients on liberal diets would be practically normal.

DR. RHOADS: I think that is quite in accord with our observations on pneumonia. Indeed, one must bear in mind, I think, that infectious disease burns up the essential substances or blocks their use in some way. It is necessary to be on guard constantly against the possibility of the patient becoming deficient in these most important enzyme systems. We are putting all of our convalescent respiratory disease patients on high vitamin therapy as quickly as they can take things by mouth.

There is a strong impression that convalescence is shortened by feeding high vitamin diets. Unfortunately, at the present time the impression isn't susceptible to quantitative measurements.

DR. CATTELL: Do you feel it is desirable to give some attention to vitamin therapy even in mild forms of infection?

DR. RHOADS: Yes, we do. As I say, until we have quantitative measurements this statement is only one of an impression.

DR. CATTELL: Is the therapy best administered in the form of a liver extract or are there other sources equally good?

DR. RHOADS: Again that is exceedingly hard to answer because we have no measures. We do not know which vitamin is burned up first. Presumably one will have good results by giving a good yeast material, provided the patient can convert it to the form in which it is used. We know about the conversion of one factor, that which goes to make up liver extract. There are many other conversions which are not so well understood.

The matter of yeast therapy is an interesting one. Dr. Dexter, associated with me, has found a most extraordinary variation in the potency of yeast. He finds that in many commercial preparations the nicotinic acid enzyme is just about dead, as shown by tests for cozymase content. The manufacturers grind up the yeast very carefully to make a palatable preparation. The procedure of grinding gives a big surface area to be oxidized, and cozymase disappears.

We have the greatest difficulty in getting a suitable yeast preparation. Quantitative measurements are not available for potency. The whole field has to be studied, I think, in much greater detail.

STUDENT: I should like to ask Dr. Rhoads what commercial product of vitamin B complex he feels is the most useful for therapeutic purposes.

DR. RHOADS: I am sorry I cannot answer that. We are using material made for us by the Fleischmann Company. That is not available generally. It is a very potent, rough kind of yeast. We have not made a careful analysis of the various therapeutic materials for sale. We have tested certain ones and there is a great variation. Our best preparation is a coarse one which comes in lumps, like grapenuts. There is not much surface area and it holds the potency better than the finely purified and ground powders. Nobody has adequate measures of the potency of the commercial preparation except by rat growth methods.

DR. CLAUDE E. FORKNER: I should like to make just one comment concerning your early remarks, Dr. Rhoads, concerning the discovery of the effectiveness of liver. I think that perhaps it precedes the studies of Howard because in the old Chinese literature there is plenty of evidence that they thought liver was very effective in the treatment of anemic persons.

DR. RHOADS: Sir Patrick Manson, the great English authority on tropical medicine, was confronted with a case of tropical sprue in Shanghai in 1880. He did not know much about the disorder but recognized the anemia. He treated the woman with iron. He called in Cantlie, a celebrated colleague, to assist him with the case and he could do no better. The woman left both her physicians and went to a Chinese Joss doctor, who cured her in two weeks. She met the two Englishmen on the street later and upbraided them for their lack of effective therapeutics. They were very much hurt and rushed to the Chinese doctor, whom they knew, and asked him what was used. He said he had administered a very fine remedy which had been employed by his ancestors for many thousands of years, the dried liver of a crow made up into a pill. It was perfectly effective, apparently. From that day on Patrick Manson included liver as a method of treating sprue in his textbook.

I think that observation supported Dr. Minot in his clinical work, as it supported everybody looking for a dietary factor curative of pernicious anemia.

DR. GOLD: Do the skin lesions of pellagra respond to nicotinic acid as well as those of the tongue? If you see a suspicious tongue would you use nicotinic acid or vitamin B complex?

DR. RHOADS: On the first question I would have to quote the experience of Smith, Spies and others, who have been treating a great many pellagrins. They feel that pellagrous skin does respond to nicotinic acid as does the tongue, up to a point. There is a strong suspicion that there is something else needed as well.

The question about sore tongue and nicotinic acid is an interesting one. We have studied well up to 100 cases of glossitis of various types. I cannot even now decide which will respond to nicotinic acid, which to yeast and which to liver extract. Many certainly do not respond to nicotinic acid. Most do respond to liver extract. This is in accord with the observation of Sebrell and his co-workers, who have shown that the cracked lips of cheilosis may be produced by lack of flavin and cured by administering flavin. We have worked nearly two years on this problem with a large number of cases now. Weissberger in Boston, who has been independently engaged in a similar problem at the Harvard Dental School, has had a similar experi-

ence. We need precise methods for measuring the deficiency, which we do not have at present.

DR. GOLD: Won't a quart of milk a day do as well as nicotinic acid or yeast for the average person under suspicion of pellagra?

DR. RHOADS: Milk is exceedingly rich in flavin. It is not very rich in nicotinic acid, apparently, judged by the animal test. A dog will get blacktongue if maintained sufficiently long on a straight milk diet.

DR. GOLD: I believe that Goldberger never found pellagra in subjects taking a quart of milk daily.

DR. RHOADS: Milk is supposed to be useful in preventing pellagra. I can only tell you that the dog will get into trouble. I haven't the figures for the nicotinic acid content of milk in mind. I am not sure they are known. Milk is not a perfect food, and it will not maintain the dog or rat in health. We are not perfectly sure, you see, in the dog, that this stomatitis which occurs is not due to lack of something else than nicotinic acid. Apparently, when you interfere with any respiratory enzymes you get stomatitis in the dog. It is not impossible that lack of iron may be a factor.

STUDENT: If you excuse the diversion to another vitamin, is there any acceptable evidence for anti-infectious action of vitamin A in human beings?

DR. RHOADS: I should think that was not possible to answer. The only acceptable papers that I have seen are those of Webster. Church is at present continuing the work on the subject in Philadelphia. I am informed that he has convincing unpublished experiments. Although the evidence is suggestive, it would require five years and a tremendous outlay of money to produce conclusive experiments. You have to have animals whose susceptibility is known precisely and they have to be handled under the most meticulous laboratory conditions. There is certainly a strong suggestion that lack of vitamin lowers the resistance of experimental animals to infectious disease.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS FORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

PENTOTHAL SODIUM.—Sodium ethyl (1-methylbutyl) thiobarbiturate.—Sodium ethyl (1-methylpropyl carbonyl) thiobarbiturate.—

The monosodium salt of ethyl (1-methylbutyl) thiobarbituric acid. Pentothal sodium differs from soluble barbituric U. S. P. (sodium diethylbarbiturate) in that one of the ethyl groups of the latter is replaced by a 1-methylbutyl group and the oxygen atom in the urea part of the molecule has been replaced by a sulfur atom.

Actions and Uses.—The actions and uses of pentothal sodium are essentially similar to those of pentobarbital sodium except that pentothal sodium is effective in smaller doses and the action is of briefer duration. When injected it is a quick-acting, general anesthetic with an early recovery period. It may be emphasized that the intravenous use of barbiturates may be a valuable procedure; but such use is potentially dangerous and should be undertaken only by experts for short operations. The use of pentothal sodium is not recommended in major operative procedures requiring long anesthesia or for office procedures. It

should be employed only by competent, experienced anesthetists or surgeons who have at their hands facilities to combat problems involving respiratory depression and carbon dioxide-oxygen balance.

Dosage.—Two or three cc. of a 5 per cent solution (from 0.1 to 0.15 Gm.) is injected in about ten or fifteen seconds. The injection is then stopped to permit the complete effect to appear, which requires from thirty to thirty-five seconds. If relaxation has not occurred, an additional 2 or 3 cc. may be injected at the same rate as before.

Caution: Aqueous solutions of pentothal sodium are not stable but decompose on standing; on boiling, a precipitation occurs.

Pentothal sodium occurs as a yellowish-white hygroscopic powder, possessing a sulfur-like odor, soluble in water and alcohol, insoluble in absolute ether, benzene and hydrocarbon solvents. An aqueous solution of pentothal sodium has an alkaline reaction to litmus.

Dissolve about 0.5 Gm. of pentothal sodium in 100 cc. of water, add an excess of diluted hydrochloric acid; collect the resultant ethyl (1-methylbutyl) thiobarbituric acid on a filter paper, wash and dry at 70 C.: it melts at 156-159 C. Incinerate about 1 Gm. of pentothal sodium; the residue responds to tests for sodium carbonate and very faintly for sulfide. Boil about 0.2 Gm. of pentothal sodium with 25 per cent sodium hydroxide solution; no evolution of ammonia occurs. Dissolve about 0.1 Gm. of pentothal sodium in 10 cc. of water, add 1 cc. of mercuric chloride: a white precipitate results, soluble in an excess of ammonia.

Dissolve about 0.5 Gm. of pentothal sodium in 50 cc. of water, add 5 cc. of diluted nitric acid and filter through paper: separate portions of 10 cc. each of the filtrate yield a faint opalescence on the addition of 1 cc. of silver nitrate solution (chloride); very slight turbidity on the addition of 1 cc. barium nitrate solution (sulfate). To about 0.2 Gm. of pentothal sodium in 25 cc. of water add 1 cc. of diluted hydrochloric acid; filter through paper: the filtrate yields no coloration or precipitation on saturation with hydrogen sulfide (salts of heavy metals).

Dry about 0.5 Gm. of pentothal sodium, accurately weighed, at 70 C., for twenty-four hours: the loss in weight should not exceed 2 per cent.

Transfer about 0.3 Gm. of pentothal sodium, accurately weighed, to a suitable Squibb separatory funnel; add 50 cc. of water, followed by the addition of 10 cc. of diluted hydrochloric acid; extract with six successive portions of chloroform using 25 cc., 25 cc., 20 cc., 15 cc., 15 cc., and 10 cc. respectively, evaporate the combined chloroformic extractions to dryness in a stream of warm air and dry to constant weight at 70 C.: the amount of ethyl (1-methylbutyl) thiobarbituric acid corresponds to not less than 89 per cent nor more than 92 per cent calculated to the dried substance.

Transfer the acidulated aqueous portions from the foregoing immiscible solvent extraction to a tared platinum dish and evaporate to dryness on a steam bath; to the residue obtained add 5 cc. of sulfuric acid; heat cautiously until the excess of sulfuric acid has been volatilized; repeat twice, using portions of 1 cc. each of sulfuric acid each time; add about 0.5 Gm. of ammonium carbonate; ignite to constant weight and weigh as sodium sulfate: the percentage of sodium corresponds to not less than 8.5 per cent nor more than 8.8 per cent when calculated to the dried substance.

Manufactured by the Abbott Laboratories, North Chicago, Illinois. U. S. patent applied for.

Amponles Pentothal Sodium 1.0 Gm. (15½ grains), Buffered with Anhydrous Sodium Carbonate 0.6 Gm.

Amponles Pentothal Sodium 0.5 Gm. (7½ grains), Buffered with Anhydrous Sodium Carbonate 0.3 Gm.

Pentothal sodium with anhydrous sodium carbonate occurs as a yellowish-white hygroscopic powder, possessing a sulfur-like odor and soluble in water. An aqueous solution of pentothal sodium has an alkaline reaction to litmus; 2.5 per cent in water has a pH of 10.4 to 10.9 when determined by the glass electrode.

Dissolve about 0.5 Gm. of pentothal sodium with anhydrous sodium carbonate in 100 cc. of water; add an excess of diluted hydrochloric acid; collect the resultant ethyl (1-methylbutyl) thiobarbituric acid on a filter paper, wash and dry at 70 C.: it melts at 156-159 C. Boil about 0.2 Gm. of pentothal sodium with anhydrous sodium carbonate with 25 per cent sodium hydroxide solution; no evolution of ammonia occurs.

Dissolve about 0.5 Gm. of pentothal sodium with anhydrous sodium carbonate in 50 cc. of water; add 5 cc. of diluted nitric acid and filter through paper: separate portions of 10 cc. each of the filtrate yield a faint opalescence on the addition of 1 cc. of silver nitrate solution (chloride); very slight turbidity on the addition of 1 cc. barium nitrate solution (sulfate). To about 0.2 Gm. of pentothal sodium with anhydrous sodium carbonate in 25 cc. of water add 1 cc. of diluted hydrochloric acid, filter through paper; the filtrate yields no coloration or precipitation on saturation with hydrogen sulfide (salts of heavy metals).

Dry about 0.5 Gm. of pentothal sodium with anhydrous sodium carbonate, accurately weighed, at 70 C., for twenty-four hours: the loss in weight should not exceed 2 per cent.

Transfer about 0.3 Gm. of pentothal sodium with anhydrous sodium carbonate, accurately weighed, to a suitable Squibb separatory funnel; add 50 cc. of water, followed by the addition of 10 cc. of diluted hydrochloric acid; extract with six successive portions of chloroform using 25 cc., 25 cc., 20 cc., 15 cc., 15 cc., and 10 cc. respectively, evaporate the combined chloroformic extractions to dryness in a stream of warm air and dry to constant weight at 70 C.: the percentage of ethyl (1-methylpropyl carbonyl) thiobarbituric acid should correspond to not less than 84 per cent nor more than 87 per cent when calculated to the dried substance.

Transfer the acidulated aqueous portions from foregoing immiscible extraction to a suitable flask, heat on steam-bath to remove the extracting solvent; add 50 cc. distilled water, previously boiled, and titrate with tenth-normal hydrochloric acid using methyl-red as an indicator: the percentage of sodium corresponds to not less than 10 per cent nor more than 10.7 per cent calculated to the dried substance.

THE CASE OF ASA BRUNSON VS. MORRIS FISHBEIN

(Concluded from page 233)

TESTIMONY OF DR. CLARENCE W. MUEHLBERGER ON
DIRECT EXAMINATION

By Mr. Harrell:

Clarence W. Muehlberger, Chicago, chemist and toxicologist, stated that he graduated in a course in chemical engineering from the Armour Institute of Technology in Chicago, receiving a degree of bachelor of science in 1920. He then did graduate work in chemistry and toxicology at the University of Wisconsin, receiving a degree of master of science in 1922 and doctor of philosophy in 1923. He is a member of the American Society for Pharmacology and Experimental Therapeutics, American Public Health Association, the Society for Experimental Biology and Medicine, American Medical Association and Society of Medical Jurisprudence. He has a laboratory in the Cook County Morgue, in Chicago, at the Cook County Hospital. He has been affiliated as staff toxicologist for Cook County Hospital since 1930, and associate professor of toxicology and pharmacology in Northwestern Medical College since 1930. He has been lecturer in toxicology at the University of Illinois College of Medicine in Chicago for five years. He has been professor and lecturer in toxicology in the University of Chicago Medical School four years, and for the last five years has been lecturer in forensic chemistry in Northwestern University Law School.

Q.—Doctor, will you tell us a little more about what the work is of a toxicologist? A.—It consists in analyzing materials from persons' bodies for poisons or in some instances analyzing medicines or any other constituent, any other material, to find out whether or not they contain poison and also to find out what they do contain.

Q.—And in a general way can you tell us what the work is of a chemist? A.—There are various kinds of chemists. There are analytical chemists, organic chemists, oil chemists. The field of chemistry is very well specialized, so the work of a chemist varies depending on what particular kind of chemistry you mean.

Q.—The chemistry which has to do with the analyzing of medicines to determine their composition. A.—The analyzing of medicine or of anything else involves the finding out what the substance is in the medicine or the substances and finding out how much of each particular substance is contained in the medicines. The first part is to find out what is in the mixture and the second to find out how much is in the mixture.

Q.—In your work, Doctor, in Chicago do you have occasion to analyze medicines? A.—Yes, that is part of my regular work.

Q.—Can you tell us on an average about how many analyses you make of medicines within the course of a given time, say within six months or a year? A.—I couldn't give you any exact figure. Certainly, since I have been in this work I have analyzed over 100 medicines.

On May 13, 1939, he met Mr. E. M. Burke in Chicago and obtained from his hands certain specimens of liquid for analysis. Besides himself and Mr. Burke, Dr. Lloyd Harris of the University of Oklahoma was there and Dr. Sidwell of the American Medical Association Chemical Laboratory. He took the specimens back to the laboratory and analyzed them. On May 17 he met Mr. James H. McCoy in the laboratory in the Cook County Morgue, Chicago. Mr. McCoy gave him a package containing a red cardboard box labeled "De Vilbiss No. 15 Atomizer." Inside the box was an atomizer and a rubber connecting tube without the rubber bulk and a 2 ounce medicine vial which had a black composition screw stopper. The medicine vial was about three fourths filled with a colorless liquid. When he first saw the vial it was sealed across the top with some white tape or paper-like material, around which was some white adhesive tape, surgical adhesive tape, bearing the pen and ink letters "F. P. M. 8-15-38."

Q.—You do not know what those figures denote do you? F. P. M.? A.—I would judge it was the initials of F. P. McCoy and the figures were the dates, eighth month, 15th day, year 1938.

Q.—Did you make a chemical analysis of the contents of these bottles together or did you separate them and make separate analyses of the bottle received from Mr. McCoy, that is, a different analysis, a separate one from that of the other two bottles? A.—I made three separate analyses, one for the contents of each of the three bottles which I have mentioned.

Q.—Will you tell us briefly, Doctor, what you did in making these analyses? A.—The first thing I did was to arbitrarily designate Mr. McCoy's specimen as sample A so I would not mix it up with samples B and C. Then I examined them by looking at them, by tasting them, by smelling them and by testing their solubility, that is the ability to dissolve them in various other liquids. I found that these three liquids were all rather oily, syrupy, colorless liquids, which had no dissolvable matter. In other words, they were clear like water but somewhat thick and oily. When I smelled them I noticed a definite odor of terpenes such as oil of eucalyptus, which has a typical odor, and some suggestion of menthol because when I smelled it I not only noticed the menthol odor but the rather cooling after effect which is typical of menthol or mint camphor. I tested the liquid by tasting and was also able to identify by this tasting a substance which tasted like oil of eucalyptus and also I noticed the cooling effect of menthol, especially in the after tasting, after the first rather terpene tasting had worn off. I then tried the various oils to see how they would react with solvents, first trying water, which I found would not dissolve to any extent any of the constituents of any of the three medicines, either A, B or C. I tried 95 per cent alcohol, which is the usual strength of alcohol used in medicine, and found that alcohol would not completely dissolve the medicine but would extract from the medicines certain fractions, which when the alcohol was evaporated off gave me a residue which had a strong odor of oil of eucalyptus and menthol and some other terpene-like odor which I couldn't positively identify. Alcohol also extracted some of the oily material, as I discovered when I took the alcohol extractions, evaporated it on a steam bath until all of the smell was gone and then examined the residue in my evaporating dish. I found it to be an oily residue, colorless, odorless and not attacked by alcohol, caustic soda or alcohol sodium hydroxide solution, which indicated it was not a vegetable oil or animal oil but mineral oil, what we call ordinary mineral oil. I then proceeded to try to take the specimens apart by selective solvents; not only did I use water and 95 per cent alcohol, but I found certain other solvents would completely dissolve all three of the medicines. For instance, anesthetic ether, such as used in hospitals, would readily dissolve all three of the medicines equally well, that acetone would dissolve all three of the medicines equally well, that ethyl acetate only partially dissolved the medicines, that glacial acetic acid would only partially dissolve the medicine, apparently extracting from the medicine only the odor principles, the material which had a strong odor, because when I took the acetic acid extract which separated out below the medicine, when I shook them together in a flask, or in a flask known as a separatory funnel, I could draw off the acetic acid layer and bring with it the materials which smelled in the medicines, the material which smelled of oil of eucalyptus, which smelled of menthol or mint camphor and which smelled of terpene-like substances. Then when the acetic acid was neutralized with caustic soda I was able to extract those with purified sulfuric ether and thereby separate them, so in this way I was able to separate the medicine in its various constituents to a fair degree to find out what materials were there. I also took the various medicines and made the studies of their physical properties. I examined the relative heaviness of the three medicines, what we call specific gravity, and found them all to be essentially the same specific gravity, within one unit in the third decimal of 0.847, because all had practically the same heaviness. In other words, they were lighter than water and about 0.85 as heavy as water at 25 degrees centigrade. I also measured the ease with which these three liquids would transmit light. We have in the laboratory an instrument known as a refractometer, which measures the refraction index of the light, which measures the speed in which light will pass through the liquid, and that figure and that value are characteristic of different liquids. I found all three of the liquids had the same refractive index, which at 25 degrees centigrade was 1.464 to within one unit of the third decimal place. So from the standpoint of physical constants and from their odor and smell and taste and behavior toward solvents, these three liquids, A, B and C, appeared to be identical; that is, they were all essentially the same type of medicines.

Q.—Did you finally complete your analysis of each of these three bottles of medicine? A.—Yes, I went further to try and estimate as best I could with the amounts of specimens

BRUNSON VS. FISHBEIN

JOUR. A. M. A.
JULY 22, 1939

approximately how much of the various constituents were present and also to satisfy myself there were no other substances present in any appreciable quantities. I distilled the specimen in a distillate flask by heating it with a gas burner until it began to boil and then cooling the vapors that came off the boiling liquid in a water cooled tube and catching the vapors as they turned back to liquid and examined them. I found with a 5 cc. specimen, which is a little over a teaspoon, I got about 0.2 cc. of distillate, which would correspond to about 4 per cent of the material I was able to drive over by the distillation process at temperatures below 300 degrees centigrade. When I heated the flask higher than 300 degrees centigrade, the colorless mixture began to darken and give off a smoke and I got more distillate which smelled of a decomposing petroleum compound, indicating the petroleum oil or mineral oil was being destroyed by the heating process. I then took another specimen of each of the three liquids and steam distilled them. I passed steam into the flask, which steam as it passed through the specimen would take with it the easily evaporated constituents of the medicines and then by cooling the material down in a condenser I was able to collect the water and with the various constituents which the steam took from the medicine. I examined these distillates to see what they contained not only by smelling and tasting them but by chemical tests and I also examined the residual liquid which was left in the flask into which I passed the steam. I found after steam distilling all of the odors had been eliminated, driven over by the steam, and the material that was left had all the properties of what we call light mineral oil or liquid petrolatum. The first distillate I collected had a strong odor of oil of eucalyptus and had oily globules which floated on the surface of the water, and on testing these with syrupy phosphoric acid, or 70 per cent, I found they would solidify, indicating and confirming the smell and taste tests I made previously, that the substances contained oil of eucalyptus. I then continued steam distillation. The next distillate had a weaker odor of eucalyptus but a more pronounced odor of menthol or mint camphor and this was confirmed by the vanillin sulfuric acid test which I took, and using a 5 per cent solution of vanillin in alcohol mixed it with some of the distillate, and putting in a test tube, dropping concentrated sulfuric acid into the bottom of the test tube with a long cylindrical dropper, so the two layers were kept separate, and where the two layers came together I found a reddish orange ring, the upper layer of which was rather lavender coated and that is a test confirming the last distillate while I could not obtain any chemical tests indicating terpenes, there was somewhat of an odor of oil of pine, but I could not be absolutely certain. It could be oil of pine and had the odor of terpene.

Q.—To sum up in few words will you tell the Court and jury what your analysis of the medicine which you received from Mr. McCoy contained? A.—The analysis together with a synthesis, which means the putting back together of the constituents being completed, I found the three materials are the same and contain about 95 to 96 per cent of mineral oil, that is known as light liquid petrolatum, colorless. Dissolved in that is a small amount of oil of eucalyptus and my best judgment of the amount of oil of eucalyptus present is around 3 cc. or 3 per cent by volume, but it might be a little lower or a little higher and there is also menthol, mint camphor, present to the extent of around 1 per cent, it might be a little higher or it might be a little lower, and there is some flavoring which I am not certain of the composition of. It is a terpene-like material which smells a good deal like oil of pine. What that flavor is I cannot be absolutely certain.

Q.—What did your analyses of the medicines which you received from Mr. Burke disclose, together with the percentages? A.—All three of the medicines as far as I could determine were exactly alike. They all contained 95 to 96 per cent—that cannot be determined with absolutely accuracy because of the difficulty in evaporation by distillation—of oil of petrolatum, approximately 3 per cent of oil of eucalyptus and approximately 1 per cent, possibly a little less, of menthol with some flavoring.

CROSS EXAMINATION

By Mr. Sweeney:

Q.—When did you arrive in El Paso, Doctor? A.—Tuesday, Tuesday of this week.

Q.—You have been here at the Hotel Hilton ever since? A.—Yes, except when I have—

Q.—Are you a member of the American Medical Association? A.—Yes, I am, didn't I testify to that?

Q.—Yes, I am just reasking the question. Do you hold an official position with the American Medical Association? No, I do not.

Q.—Are you connected with it in any other way than be a member? A.—No, I just happen to be one of the few not M.D.s who are members of the society.

Q.—Do you do any considerable amount of work for them? A.—No, this is the first time I have been asked to be of any help to them in any way.

Q.—Who asked you to come out here, Doctor? A.—Mr. Burke.

Q.—Your expenses are being paid by Mr. Burke or the American Medical Association? A.—As far as I know Mr. Burke is paying them. You will have to ask him about that.

Q.—You have received pay for the analyses you made? A.—I have not.

Q.—You expect to? A.—I expect to be paid for my time, that is customary.

Q.—Doctor, who have you talked to since you have been in El Paso with reference to your analyses? A.—Well, I probably have spoken to a number of people. I don't know that I can tell you all of the people I have spoken to. I have spoken to the various attorneys, Mr. Harrell and his associates and believe I have talked to Mr. McCoy and I may have said something to Dr. Fishbein. Up until this morning I probably said something to Dr. Harris and possibly others. I couldn't be certain.

Q.—Did you and Dr. Harris have a talk in Chicago with reference to the analysis that he was to make and you were to make? A.—I expect we did. We certainly both understood that we were to make a chemical analysis of the substance.

Q.—Did you make any comparison with reference to your result and his result? A.—Not until after the results were done.

Q.—Did you talk to Dr. Leech? A.—Yes, I have talked to Dr. Leech.

Q.—Did Dr. Leech tell you what chemical analysis was made by Dr. Schoeffel? A.—I believe he did. I am not certain.

Q.—He indicated to you the constituents that Dr. Schoeffel had determined or ascertained was in the medicine? A.—I think he did.

Q.—When you went to Mr. Burke's office who told you to go there and what was the occasion? A.—As far as I know Mr. Burke told me. I am not clear on that.

Q.—You do not remember? A.—No.

Q.—You do not know what the occasion was for you to go there? A.—As I recall it Mr. Burke or some one of his firm called me up and asked me if I would participate in the case at least he made arrangements to be there and to receive the samples from his hands personally.

DEPOSITION OF MAURICE TROUT: DIRECT EXAMINATION
Taken in Little Rock, Arkansas, on May 8, 1939.

Questions by Mr. Harrell:

Maurice Trout, advertising clerk, *Arkansas Gazette*, testified that he has charge of the old newspapers that are ordinarily kept in what's commonly known as "the newspaper morgue." He identified issues containing an advertisement headed "A Prominent Little Rock Physician," which advertisement is signed "Arkansas Drug Company," also *Arkansas Gazette*, Friday, Aug. 10, 1923, an advertisement over the name of "Arkansas Drug Company," which is headed "One of Many Testimonials to Doctor Asa Brunson's Treatment for Tuberculosis," also *Arkansas Gazette*, Saturday, Aug. 11, 1923, an advertisement headed "Another Testimonial to the Doctor Asa Brunson Tuberculosis Treatment," by the "Arkansas Drug Company."

Mr. Reynolds:—At this time we wish to read to the jury one paragraph from Defendant's Exhibit 13, which has been identified by the plaintiff in this suit, an article entitled "New Tuberculosis Cure Tried in El Paso with Results Beyond Belief." It is the *El Paso Times* of June 19, 1921. The plaintiff's testimony being the material contained in said article was furnished to the writer by him.

[After debate the Court permitted the reading.]
Mr. Reynolds:—The complete paragraph relating to Mr. McCrary reads:

"One of the remarkable cures effected in El Paso was that of James F. McCrary, a former service man, now living in El Paso. Mr. McCrary, who is 25 years old, was formerly

a cattleman at Hamilton, Texas. He contracted tuberculosis after a gas attack in France in November 1918. His case was diagnosed by Dr. Bolding as tuberculosis in August 1920, and later the diagnosis was confirmed by Dr. Shortall at Albuquerque, N. M., and by physicians in the army vocational department at Dallas. He was found to be in no condition to take vocational training and in January of this year he was recommended for full compensation, which he received. He began taking the Holderness treatment April 4 and was discharged as cured May 17. He is now taking vocational work in El Paso. In response to an investigator's questions Mr. McCrary wrote the following:

"To whom it may concern: This is to certify that I was in the Sixth Marines and was gassed in France in November 1918. Had difficulty at times in breathing until I was treated by Drs. Holderness and Brunson. I have not experienced any trouble since the first treatment and have been discharged over thirty days. I was also diagnosed as a tubercular by the army board of surgeons and have been discharged by Drs. Holderness and Brunson as cured so far as can be determined at this time."

Mr. Quaid:—We would like for the record to show we have a further objection, that it was the Holderness treatment instead of the Brunson treatment.

The Court:—Well, the Court is waiting for that connection. The Court, is informed that it will be connected up. The Court will say right now if it is not shown to be a treatment that Dr. Brunson was connected with—we have had testimony in the case they were connected together at a certain time—if it was distinctly a Holderness treatment it would not be chargeable to Dr. Brunson.

Mr. Reynolds:—May I refer the Court to the testimony already in the case regarding an oily substance. That is what I had in mind.

The Court:—We will endeavor to gather together in a simple summary this matter as we go along.

Mr. Reynolds:—The deposition of James F. McCrary, taken before Jack K. Tingle, a Notary Public in and for the County of Dallas, in the Dallas National Bank Building.

DEPOSITION OF JAMES F. MCCRARY: DIRECT EXAMINATION

By Mr. Harrell:

James F. McCrary, Dallas, Texas, formerly in the warehouse brokerage business, until three years ago, when he had to go back to the hospital, stated that he was acquainted with Dr. Asa Brunson of El Paso. He first became acquainted with him sometime in 1921 in a drug store in El Paso, Texas. He was associated with two other men in the drug business and was a "silent partner." He knew Dr. Bolding very well as his family physician at Hamilton, Texas. He and Dr. Bolding went to El Paso at that time on account of lung trouble.

Q.—Now, let's get to the meeting with Dr. Brunson in the drug store. Tell us the circumstances under which you met him there. A.—Well, he was opening an office—I forget the name of the building but it was just around the corner from our drug store.

Q.—Was that the Caples Building? A.—I believe that is the name; I am not quite sure.

Q.—Did you have a conversation with Dr. Brunson at that time? A.—On several occasions I had conversations with him before I started taking treatments from him.

Q.—Did you discuss with him on the occasion of this first meeting the matter of taking "T. B." treatments? A.—No, sir.

Q.—Do you recall when you first discussed with him about being treated for "T. B."? A.—Well, he stayed around the drug store there for a month or six weeks and he wasn't permitted to practice in Texas because he didn't have a license, so he persuaded Dr. Bolding to use his license and to go into the office with him so that they could open an office and practice medicine. In other words, Dr. Bolding was to write the prescriptions or you know what is the necessary procedure that they had to go through until he could get his license in Texas, and Dr. Bolding went up there and he started taking the treatments and he gained 7 or 8 pounds, but he never was convinced that it was—he told me that it was a stimulant more than anything else—

Mr. Quaid:—Just a minute.

Mr. Reynolds:—We won't read the balance of that answer. It is hearsay.

Q.—Did you take it? A.—So I took the treatment for about five weeks. Up in his office one day—

Q.—Well, now, wait a minute; tell us about the technic, how he administered the treatment—just what did the Doctor do? A.—With an atomizer.

Q.—Describe how he used the atomizer? A.—He put the atomizer in my throat and in my nose, in nostrils and—

Q.—When he put the atomizer in your mouth, what did you do, if anything? A.—Well, at times, I would swallow some of the stuff and it is pretty darn bitter; that's one thing.

Q.—I mean by that, what would you have to do in order for the medicine to enter? A.—Inhale.

Q.—Inhale? A.—Yes.

Q.—And what else? A.—That was all there was to it.

Q.—How often would you take these treatments? A.—Every day.

Q.—Did you know what the treatment consisted of, the ingredients of the treatment? A.—I had no idea.

Q.—The doctor never told you the composition of the fluid? A.—No, sir; secret formula that he was supposed to have.

Q.—And you took this treatment for how long a period of time did you say? A.—Four or five weeks.

Q.—And you took them twice a day for that length of time? A.—Once a day.

Q.—Did you pay the doctor anything for the treatments? A.—Not a dime.

Q.—He didn't charge you anything? A.—No, sir. He did ask me to encourage others.

Q.—Mr. McCrary, did you have any conversations with Dr. Brunson during the time—? A.—Yes; every day.

Q.—that you were submitting to the treatments? A.—Yes; every day.

Q.—I am referring to conversations as to whether or not the treatment was doing you any good? A.—Well, he—I don't remember about that, but I will say this; he never gave me a chest examination all of the time I was there, either before I took the treatment or afterwards.

Q.—You mean that he didn't examine you at all? A.—No, sir.

Q.—At any time? A.—No, sir.

Q.—He didn't do anything at all in the way of examination? A.—Nothing at all only give me the inhalations; he didn't know whether I had lung trouble or not only from what the others said—just my general record.

Q.—Did you take any medical records with you there? A.—No, sir; none at all.

Q.—Now, prior to going to Brunson, had you been examined before by any physician? A.—Yes; I had just left the hospital at Albuquerque, New Mexico, about two months previous to that.

Q.—Did they examine you while there? A.—Yes.

Q.—Did they diagnose your ailment? A.—As lung trouble, yes; also by Dr. Bailey at Hamilton.

Q.—What had been your physical condition prior to that time?

The Court:—We have been laying off of this proposition of a layman saying what was his condition. We don't want to open this thing up.

Q.—What do you mean by "this thing"? A.—Headlines in the paper came out. The medical board, knowing that I had taken this treatment, called me up there and they questioned me about it, and they explained to me that the reason that I was gaining weight was the psychology it would have on me, the possibility of gaining some relief.

Q.—I show you, Mr. Witness, the newspaper article with the headline "New Tuberculosis Cure Tried in El Paso with Results Beyond Belief," which is purported to have appeared in the El Paso Times newspaper of June 19, 1921, and I will ask you if you have ever seen that article before? (Counsel hands paper clipping to the witness.) A.—Yes; I saw that all right.

Q.—So you recall seeing this article (indicating)? A.—Yes; I saw that article.

Q.—Now, I notice here, Mr. Witness, that there is, among other statements in this article a specific reference to a Mr. James F. McCrary, a former service man, now living in El Paso; that particular part of the article is headed "Ex-Marine Saved from Grave"; I will ask you if that James F. McCrary, referred to in the article is yourself? A.—Yes, sir.

Q.—I will ask you to read that portion of the article pertaining to yourself and tell us, if you please, if the statements contained therein are true? A.—I was with the Sixth Marines; I was gassed but I wasn't relieved from them as a "cure"; I stopped taking the treatment.

Q.—By "them," who do you refer to? A.—Dr. Brunson and Dr. Holderness.

Q.—Drs. Holderness and Brunson? A.—Now, then, I would like to make a correction. This statement is supposed to be sworn to that I signed, see. I would like to tell you how that came up.

Q.—You mean the statement that is referred to in the article which you are now holding in your hand? A.—Yes, sir.

Q.—You mean the statement which is headed "To Whom it May Concern"? A.—Yes; I would like to tell you how he got that statement.

Q.—And your explanation is that Dr. Brunson got you—? A.—I went up to his office one day; — — —

Mr. Quaid:—Just a minute now. Your Honor please, that answer there is not responsive; in fact it is not based on any question. It was a question started by counsel and never was completed.

Mr. Reynolds:—Counsel was interrupted by the witness there obviously.

Mr. Quaid:—It is not responsive.

The Court:—What is the purpose, on what ground do you offer all of this matter?

Mr. Reynolds:—Here is the theory—

The Court:—Is there any statement Dr. Brunson furnished—was not asked when he was on the stand—I can't see the materiality of a lot of that testimony.

Mr. Reynolds:—Well, Dr. Brunson did identify that article, and whether or not he furnished the information this witness identifies that statement which further connects Dr. Brunson. That statement is published, then he goes on to show how that statement was procured, and to show Dr. Brunson's general character, reputation and advertising. Among other things it is in mitigation of damages.

The Court:—No. I will have to hear from you out of the hearing of the jury. Have you not some other deposition? The Court wants to get along with as much rapidity as we can. The Court has serious question about a large portion of that deposition, and would like for you gentlemen to carefully consider it before you undertake to offer it.

TESTIMONY OF DR. F. P. MILLER ON DIRECT EXAMINATION

Questions by Mr. Brown:

Dr. F. P. Miller stated that he has resided in El Paso, Texas, since 1904. He graduated from the Medical Department of the University of Texas in 1899. He is a member of the local and of the state and of the American Medical association. He met Mr. McCoy and Sadie Hayes and gave a bottle of medicine to Mr. McCoy in the presence of Sadie Hayes. The medicine was obtained from Miss Hayes in August. He marked the bottle F. P. M. with the date.

Q.—Do you know, are you acquainted with the general reputation of Dr. Asa Brunson, the plaintiff in this case, in this community as a physician and surgeon? A.—I have met him a few times, very slightly.

Q.—Are you acquainted with his general reputation? A.—Yes, sir.

Q.—Is that good or bad? A.—For the treatment of diseases as a doctor, it is not good.

Mr. Quaid:—I would like to exclude that answer, it wasn't responsive.

The Court:—It is not responsive, the question is whether it was good or bad.

Mr. Brown:—That is right, it is not responsive.

The Court:—Reform the question.

Q.—Do you know the general reputation of Dr. Asa Brunson, the plaintiff in this case, in this community, with reference to the practice of medicine and comporting to the ethics of the American Medical Association, general ethics of the medical practice?

Mr. Quaid:—I don't think we are bound by the ethics of the American Medical Association.

The Court:—The Court sustains the exception.

Q.—Strike out the words American Medical Association. Do you know the general reputation of Dr. Asa Brunson, the plaintiff in this case, in this community, as to being an ethical practicing physician and surgeon? Answer that yes or no, do you know the general reputation? A.—Yes, sir.

Q.—Is it good or bad? A.—It is bad.

CROSS EXAMINATION

By Judge Sweeney:

Q.—When you answered with reference to his ethics, you know his reputation, what do you mean, Doctor, by his ethics? A.—His general demeanor in regard to the practice of medicine, claiming to cure tuberculosis with inhalation of oil.

Q.—And you think that a man who claims to cure anything is not ethical? A.—By a secret remedy, I consider it unethical.

Q.—Doctor, when you came here you advertised a whisky cure? A.—No, sir.

Q.—Never did? A.—No, sir.

Q.—Didn't you specialize in curing for liquor-habits? A.—No, sir, other people did it for me.

Q.—You never advertised at all? A.—No, sir.

Q.—You had other people advertise for you? A.—I read a paper before the medical society on it.

Q.—You are a member of the A. M. A. organization? A.—Yes, sir.

Q.—You are also a member of the local, the state and the national? A.—Yes, sir.

Q.—What position, if any, do you hold with the local? A.—I have no official position at this time with the local association.

Q.—You have had in the past? A.—Yes, sir.

Q.—What was it? A.—Secretary and president and delegate.

Q.—What do you hold or have you held with the state medical association? A.—President and delegate.

Q.—What have you held or do you now hold with the national organization? A.—I have none.

Q.—Have you held any in the past? A.—No, sir.

Q.—You obtained this medicine from Miss Hayes, is that the name? A.—Sadie Hayes.

Q.—How long was it in your possession? A.—Just the same day.

Q.—What? A.—The same day.

Q.—How did you come to get that medicine, Doctor? A.—We were discussing it.

Q.—Who are "we"? A.—Miss Hayes and I.

Q.—You were discussing Dr. Brunson, were you? A.—I asked her if she had any of the remedy and she said no.

Q.—Did you send her out to get some of the remedy for you? A.—I asked her if she could secure a bottle and she said she thought she could.

Q.—Who had requested you to try and secure a bottle? A.—I was very much interested.

Q.—And in this case now? A.—Certainly.

Q.—You are very much prejudiced in favor of the defendant, Dr. Fishbein? A.—I try not to be.

Q.—I asked if you are? A.—I would say no.

Q.—You are absolutely impartial? A.—As far as a man can be.

Q.—How far can you be? A.—All the way.

Q.—But you are very much interested? A.—Yes, sir.

Q.—What is the nature of your interest? A.—If Dr. Brunson or any one else has a cure for tuberculosis, I would like to know it.

Q.—That is the extent of your interest? A.—Yes, sir.

Q.—You want to see whether or not he has a cure, is that the idea? A.—Yes, sir.

Q.—Now, Doctor, you have talked considerably about Dr. Brunson, haven't you? A.—Very little, Dr. Brunson and I just are acquainted. I don't think I met him three times in my life.

Q.—You have discussed him various times and denounced him? A.—I said I didn't believe his remedy was a cure for tuberculosis, and I still think that.

Q.—How did you refer to him; you did make statements? A.—Just like that, I didn't believe he had a cure for tuberculosis.

Q.—You have been going around secretly, fighting Dr. Brunson? A.—No, sir.

Q.—And seeking to condemn his practice? A.—No, sir, I have done very little of it.

Q.—When did you meet Mr. McCoy? A.—I can't say the first time, but this last year, in the middle of the year, July or August.

Q.—Did he just wander in your office or did you send for him? A.—He came to see me.

Q.—Why did he come to see you? A.—He was looking up evidence in this case.

Q.—And he had heard about your talk? A.—I imagine that the central office gave him my name.

Q.—You had communicated with the central office? A.—Not at that time about this.

Q.—He came to see you, and what did he request of you? A.—For me to help or assist him in any way in securing evidence for or against and get some of this remedy.

Q.—Did you seek any evidence for? A.—For the remedy. Q.—With reference to Dr. Brunson's treatment, the efficacy of his treatment? A.—I haven't heard that discussed for years.

Q.—You sought for evidence against the efficacy of his treatment? A.—I wanted to get some of the oily spray he is using.

Q.—You sent this young lady out to get it? A.—I asked her to get it.

Q.—She was in your employ? A.—No, sir.

Q.—At no time? A.—I think one time, when my stenographer was away, she worked there.

Q.—She was a patient of yours? A.—She was a patient of mine for a long time.

Q.—Did you predicate your statement that his reputation was bad because he claimed to have a cure for tuberculosis? A.—Mainly, one that he wouldn't publish the formula and let the rest of us know what it was.

Q.—One you couldn't get? A.—Yes.

Mr. Reynolds:—At this time we would like to read certain testimony from Defendant's Exhibit D-14, which was identified by the plaintiff. I wish to read one of his testimonials right now. "El Paso Times, August 10, 1924." The title of the article is "Shadows of the Dark Ages Still Cast Their Pall," and down after the body of it there are several testimonials; we are reading one:

Little Rock, Ark.
Nov. 17, 1922.

Mr. W. K. McMullen,
Little Rock, Ark.

Dear Mr. McMullen:

Two of our Sisters have been treated by Dr. Brunson for tuberculosis. One Sister has entirely recovered and the other has been greatly benefited by the treatment.

Sister Superior
Mount Saint Mary's Convent
and Academy.

DEPOSITION OF SISTER MARY FIDELIS

Direct examination taken on May 1, 1939, at St. Louis, Mo.

Questions by Mr. Harrell:

Sister Mary Fidelis of the Convent of Mercy, Webster Groves, Mo., stated that she is one of the councilors on the provincial council of the convent. She lived in Little Rock, Ark., in 1923 in Mount St. Mary's Academy, where she was Mother Superior. She was acquainted with Sister Rosalie Bradley in 1923 in St. Mary's Convent in Little Rock, Ark. She died in May 1923 of tuberculosis.

Mr. Quaid:—I object to that.

The Court:—The Court sustains the exception.

Q.—Where was she when she died? A.—Mount St. Mary's Academy, Little Rock.

Q.—I show you what purports to be page 7 of the *Arkansas Gazette* of Little Rock, Arkansas, Saturday, August 11, 1923, which has been marked Defendant's Exhibit A of this date, and ask you to refer to an advertisement in the upper right hand corner of the exhibit with the heading "Doctor Asa Brunson. Tuberculosis Treatment." Do you see that? A.—I do.

Q.—And I notice that in that advertisement there is a testimonial which reads as follows:

November 17, 1922.

Mr. W. K. McMullen,
Arkansas Democrat,
City:

Dear Dr. McMullen:

Two of our Sisters have been treated by Dr. Brunson for tuberculosis. One Sister has entirely recovered and the other has been greatly benefited by the treatment.

Signed Sister Superior,
Mount St. Mary's Convent and
Academy, Little Rock, Ark.

Q.—Do you know anything about that testimonial? A.—I have no recollection whatever of it.

Q.—Can you recall of ever signing such a document or testimonial? A.—No, I cannot.

Q.—And on that date, November 17, 1922, you were the Mother Superior of Mount St. Mary's Convent and Academy, were you not? A.—Yes, sir.

Q.—Do you know of any other Sister connected with Mount St. Mary's Convent who died of tuberculosis along about that time or afterward? A.—No, I do not, I just cannot recall the date of death. It was within that six years, but I could not tell you what date.

Q.—Do you know what doctor treated Sister Rosalie Bradley for tuberculosis? A.—No, that I don't remember either. I remember there was a doctor came to Little Rock by the name of Brunson. I just remember the name and I know Sister consulted him and went to his office but I cannot tell you now whether she was under the care of any other doctor or not. I do not carry things in mind that length of time.

Q.—And you do not recall of having signed any such testimonial as appears here on Defendant's Exhibit A, is that right? A.—No.

Q.—If there had been a testimonial of this sort given would it have been signed as this one is signed? A.—No, not customarily, not usually.

Q.—Customarily and usually how do you sign in your capacity as Sister Superior? A.—The individual name.

Mr. Quaid:—We offer the cross interrogatories propounded to Sister Mary Fidelis, Convent of Mercy, Webster Groves, Missouri.

Fourth Cross Interrogatory:—Is it not a fact that the statement given by a Catholic sister was a testimonial given by Mother Ursula, who was then Sister Superior, Mount St. Mary's Academy, Little Rock, Arkansas, and she is now at St. Edwards Mercy Hospital, Fort Smith, Arkansas? A.—I know nothing of such a testimonial.

Fifth Cross Interrogatory:—If you answer the foregoing interrogatory in the affirmative, then state if it is not a fact that the testimonial referred to Sister Philippa, who was critically ill with tuberculosis and was sent to a Catholic infirmary to remain until she died, at Hot Springs, and that Mother Ursula then communicated with Dr. Brunson and he agreed to treat her, without charge; that Sister Philippa had tuberculosis of both lungs, had about twenty-five tubercular abscesses on her neck and chest, a few of which had been lanced and would not heal; that on the 3d day of July 1922 Sister Philippa began treatment by Dr. Brunson, that in three weeks thereafter the abscesses were cured, that after two months' treatment of her lungs she was dismissed by Dr. Brunson, a completely cured case. She resumed teaching on or about the 15th of September 1922, and has been well and teaching ever since. A.—I have no recollection of it.

Sixth Cross Interrogatory:—Is it not a fact that Sister Philippa is now Sister Superior at St. Anne's Convent, Fort Smith, Arkansas, alive and well seventeen years after her cure by Dr. Brunson. A.—No, she is not.

RE-DIRECT EXAMINATION

Q.—Again, I want to ask if you were Sister Superior of Mount St. Mary's Academy, Little Rock, Arkansas, on November 17, 1922? A.—I was.

Q.—And were you also Sister Superior of Mount St. Mary's Academy, Little Rock, Arkansas, on August 11, 1923? A.—I was.

Q.—When was Mother Ursula Sister Superior of Mount St. Mary's Academy? A.—From 1932 to 1938.

Q.—Was she at Mount St. Mary's Academy, Little Rock, Arkansas, in 1922 and 1923? A.—Yes.

Q.—What did she do there? A.—She was the Mother Purser.

Q.—And was Sister Philippa there at that time? A.—She was, yes.

Q.—In what capacity? A.—Teacher.

Q.—Is Sister Philippa now Sister Superior at St. Anne's Convent, Fort Smith, Arkansas? A.—No, she is not.

Q.—Do you know where she is now? A.—Yes, she is teaching at the Immaculate Conception School in Fort Smith.

Q.—Do you know what the condition of her health is now? A.—It is fairly good.

Mr. Reynolds:—I want to read another testimonial in the same exhibit.

Pulaski County Hospital,
Little Rock, Ark.,
November 24, 1922.

Dr. Asa Brunson,
Little Rock, Ark.

Dear Doctor:

It gives me pleasure to recommend your treatment to any one afflicted with tuberculosis, as I have seen some very remarkable results from your treatment in the patients treated at the County Hospital.

Wishing you continuous success in your great undertaking.

Fraternally yours,

H. O. Turrentine, M.D.,
Assistant Superintendent.

DEPOSITION OF DR. HUGH OLIN TURRENTINE ON DIRECT EXAMINATION

Taken May 8, 1939, at Little Rock, Ark.

Questions by Mr. Harrell:

Hugh Olin Turrentine, North Little Rock, Ark., specialist in eye, ear, nose and throat, M.D., attended Kansas City College of Medicine and Surgery and Arkansas University and was admitted to practice in Arkansas in 1920.

Q.—You are acquainted with Dr. Asa Brunson? A.—Yes, sir.

Q.—When did you first become acquainted with him? A.—I became acquainted with him when I went out to the Pulaski County Hospital as assistant superintendent under Dr. Mason.

Q.—And when was that? A.—I believe it was in the year 1922, if I am not mistaken, sir.

Q.—And how long were you out there as assistant superintendent at that hospital? A.—I think it was between six and nine months, if I am not mistaken.

Q.—Did you have any dealings with Dr. Brunson during the time you were out at the Pulaski— A.—Some.

Q.—hospital? A.—Some.

Q.—What was the nature of those dealings, Doctor? A.—Well, I examined patients down there twice at his request.

Q.—Whose patients were those? A.—Pulaski County, I presume.

Q.—What interest did Brunson have in those patients? A.—He was—if I understand it right, he asked Dr. Mason to give him permission to treat the tubercular patients for a period of time—certain length of time.

Q.—To treat his patients? A.—The patients at the Pulaski County Hospital.

Q.—And do you mean, Doctor, that Dr. Brunson requested Dr. Mason to— A.—Allow him the privilege—

Q.—allow him the privilege of administering the Brunson treatment— A.—That's right.

Q.—to the patients in the Pulaski Hospital? A.—That's right.

Q.—And do you know that that was done? A.—I know that he treated some patients out there.

Q.—Do you know just when that was? Fix the time— A.—I can't—

Q.—as near as you can. A.—It was about 1922, because that was the time I was out there.

Q.—Did you personally have anything to do with the treatment of these patients, that is, the administering of the Brunson treatment? A.—No, sir. I don't know what it consists of, even.

Q.—Doctor, I show you page five of the El Paso Times of Sunday, August 10, 1924, which has been marked "Defendant's Exhibit 22, for identification" on the taking of the deposition of the Plaintiff, Dr. Asa Brunson, in El Paso, on March 8, 1939, and I refer you to what appears to be a testimonial in the lower left corner of this exhibit and I will ask you if you can identify that testimonial. I am referring to the testimonial over the typed—over the printed name "H. O. Turrentine, M.D., Assistant Superintendent." A.—I signed the letter for him.

Q.—You did sign a letter for him? A.—I did.

Q.—And when was that? A.—That was in 1922—like it says there, November 1922.

Q.—Was this the letter that you signed? A.—I can't say.

Q.—Now— A.—He asked Dr. Mason for a letter of recommendation as to what the treatment was and Dr. Mason talked to me and I told him, well, I wouldn't mind giving him a letter, but I didn't know what it was, though, or anything about it. He had the stenographer there to type the letter—Dr. Mason wrote one. I said about the things you see in there. She typed it and I signed it. I doubt if I ever read it. The lady in the office typed it. Anyway, I signed it, because I signed one for him. I can't say whether this is the one I signed or not.

Q.—How long had Brunson been treating those patients at the time you signed this letter? A.—I couldn't say.

Q.—Did you have occasion—or, did you observe the treatment of those patients at that hospital? A.—I examined them twice—not all of them, but a few of them.

Q.—Examined them before they submitted to the treatment? A.—No, sir.

Q.—Or afterward? A.—Afterward.

Q.—Did you examine them before? A.—No, sir.

Q.—Before the treatment. A.—I had not.

Q.—How many of them did you examine? A.—I imagined I examined about five.

Q.—How long had that five been— A.—I couldn't say.

Q.—there submitting to that treatment? A.—I couldn't say, because I don't know.

Q.—Have you observed the action of Brunson's T. B. remedy on any other patients since that time? A.—I have not.

Q.—Tell us, Doctor, just why you gave Dr. Brunson this testimonial. A.—Well, Dr. Mason had seen the patients and he was talking to me about it and said that he thought that Brunson was getting some results from it—the treatment out there. I didn't know what the treatment consisted of, or anything else—only I knew they were in bed—rest, sunlight, things like that—proper diet. And I didn't know what the

treatment consisted of, and I examined them and those that I examined were free of temperature, and I didn't hear anything particular in the lungs at the time of the examination—however, I didn't see the x-ray or fluoroscope of them, or the laboratory report from the throat before or after.

Q.—Did you continue to observe those same patients— A.—I did not.

Q.—afterward? A.—No, sir.

Q.—So you couldn't say what caused the drop in temperature? A.—I couldn't.

Q.—And you couldn't say, Doctor, whether or not these persons had arrested cases of T. B.? A.—I couldn't say whether they had tuberculosis or—whether they had it or not.

Q.—You couldn't say about that—if they had tuberculosis when they first came to the hospital? A.—I couldn't. I did not examine them.

Q.—Did you give Dr. Brunson any other letters besides this one here? A.—I did not—that I know of.

Judge Sweeney:—We will offer the cross interrogatories.

Sixth Cross Interrogatory:—If you state that Dr. Mason was superintendent, state whether or not Dr. Mason is now alive. A.—He is dead.

Thirteenth Cross Interrogatory:—State whether or not it is a fact that you gave Dr. Brunson a testimonial highly recommending his treatment and the results obtained by the patients from the administration of his medicine. A.—I gave Dr. Brunson a recommendation—a letter of recommendation, recommending the treatment.

Fourteenth Cross Interrogatory:—Is it not a fact that shortly after commencing the treatment with Dr. Brunson's formula within a very short period of time the temperature became normal, that within the course of three or four weeks the appetite very materially improved, patients became stronger and took on flesh, that immediately succeeding that and within the period of about four weeks those patients who had hemorrhages ceased to have hemorrhages and that they advanced to a normal condition of health extremely rapidly?

Mr. Reynolds:—That is about a triple or quadruple form of question.

Judge Sweeney:—He says here unless they are identified more definitely.

Mr. Reynolds:—Unless they are identified, too. We renew our objection to that.

The Court:—Your urge the objection at this time?

Mr. Reynolds:—Yes.

The Court:—The Court sustains the exception.

Judge Sweeney:—If the Court please, on direct examination the statement was made that the patients were clear of temperature, he had examined four or five and they were clear of temperature.

The Court (reading answer):—In view of the answer, I will overrule the exception.

A.—Well, might I answer it this way, by saying the patients I examined were about five, which I examined twice, and at the time of examination they were clear of temperature.

Twenty-Fifth Cross Interrogatory:—Is it not a fact that you and Dr. Mason were both, as doctors and professional men, certain of the fact that the Brunson remedy cured tuberculosis? A.—I can't answer for Dr. Mason—and for myself, I do not know.

Twenty-Eighth Cross Interrogatory:—Is it not a fact that, after Dr. Brunson ceased individually in administering the formula, the hospital procured a gallon of Dr. Brunson's formula and that you and Dr. Mason administered same to the patients? A.—I can't say whether the hospital purchased any of this medicine or not. I do not know whether Dr. Mason administered to these patients or not, but, personally, I did not.

Thirty-Sixth Cross Interrogatory:—What is the customary treatment for tuberculosis in use by physicians in this country? A.—Well, most of it is rest, proper diet, proper hygienic conditions, sunshine, fresh air—well, you got "proper food" down there—proper food will consist of all the different vitamins that go into it to build up a person.

Friday, June 2

The Court:—The defendant may call the next witness or introduce the next testimony.

Mr. Reynolds:—At this time the defendant wishes to introduce, and read in evidence, a part of the last page of Defendant's Exhibit 7, which is a pamphlet issued by Dr. Brunson, according to his testimony, during the year 1929, entitled "Tuberculosis." On the last page, under the heading "Pleasant Patients," this statement: "These are names of a few of Dr. Brunson's patients who have recovered." There are listed: Mr. George Hurst, Box No. 551, Ozona, Texas; Miss Anna Marie Hale, 910 N. Oregon, El Paso, Texas; Mrs. S. G. Auld, 1717 Dakota, El Paso, Texas.

Mr. Reynolds:—At this time we also wish to read an additional paragraph from what has been called in this trial the Griffin article in the El Paso Times, June 19, 1921. Do you have any objection to that paragraph about Mrs. Clark?

Mr. Quaid:—We have already objected to the whole article.

Mr. Reynolds:—Under the headline "Experience of Woman Physician."

(Reading): "Among the most interesting cases treated by Drs. Brunson and Holderness in El Paso is that of Dr. Margaret Holliday Clark, sister of Attorney Robert L. Holliday. Mrs. Clark is herself a practicing physician and met with remarkable success at Austin, Texas, until taken ill five years ago. She steadily declined, despite the most expert medical treatment that could be obtained, until her life was despaired of. She heard of the Holderness treatment and determined to try it. A nurse was sent to her home at Austin with a supply of the medicine and Dr. Clark began improving at once. Within a week she was able to travel to El Paso and is continuing to take the treatment. Hopes are held out for her recovery, despite her five years' illness and the fact that she weighed only 50 pounds when she began the treatment."

DEPOSITION OF DR. W. A. DAVIS: DIRECT EXAMINATION

Questions by Mr. Harrell:

W. A. Davis, Austin, Texas, has been registrar of vital statistics of the state of Texas since 1928.

Q.—Now, Doctor, tell us briefly what you do in your work as registrar of vital statistics for Texas. A.—Well, the birth and death certificates are filed with the local officials in the different rural districts and cities and forwarded by them to the state bureau or the state registrar, at the end of the following month; and it is the duty of the state registrar to proof-read those records to see that they are complete and correct and, if not, to secure the completion or correction of the records if possible and then to preserve the record in such a way that it may be available for future use.

Q.—Doctor, assume that a person should die in El Paso, Texas; would you have a record of that death here in your office in Austin? A.—I would unless the law were violated and they buried the body without filing a death certificate.

Q.—Doctor, I will ask you to look at your records and tell us, please, if you have a death certificate of a person by the name of George B. Hurst, H-u-r-s-t. A.—Yes, sir, we have that record under No. 27114 for the year 1934, filed with the state bureau on July 12, 1934.

Q.—You say you have that record? A.—We have.

Q.—Have you a death certificate showing that death in your files? A.—This is a death certificate.

Q.—Yes, sir.

Mr. Reynolds:—It was marked Defendant's Exhibit 1 as of this date.

Q.—Now, Doctor, will you please refer to your records and tell us if you have a death certificate covering the death of one Vassie Aulds, A-u-l-d-s? A.—I have, under No. 54931, filed with the state bureau on January 12, 1934.

Q.—And that is part of the files and records of your office at the present time, is it? A.—Yes, sir.

Mr. Reynolds:—That was marked Defendant's Exhibit 2.

Q.—Now, Doctor, will you refer to your records and tell us if you have a death certificate covering the death of Anna Marie Hale? A.—I have, under No. 17380 for 1934, filed May 12, 1934.

Mr. Reynolds:—That was marked Defendant's Exhibit 3 and identified.

Q.—Now, Doctor, will you tell us if you have a record of the death of Margaret Holliday Clark? A.—I have, under No. 35118, filed in 1921, but this record does not show when the certificate was forwarded to the state bureau, for the reason that in 1921 the certificates were not stamped as filed. Do I make myself plain? That was not begun—we did not begin to stamp anything on them until 1928, I believe it was, so it is impossible for me to state when that record was received, but this date here (indicating) will show when it was filed in El Paso.

Q.—That is the date shown in the lower left hand corner as being 1-9-22, in other words, January 9, 1922. Is that what you mean? A.—That is what I mean; that is the date on which it was filed in the registrar's office in El Paso.

Q.—I see. Well, Doctor, the original of this death certificate is now a part of the files and records of your office as registrar, is that correct? A.—It is.

Mr. Reynolds:—That was marked Defendant's Exhibit 4. All of these having been substituted, photostatic copies having been substituted for the originals.

Q.—Now, Doctor, will you refer to your records and tell us if you have a death certificate covering the death of William Terry Bolding? A.—I have, under No. 31638 in 1925; but it does not show the date on which that record—that certificate was sent to the state bureau. The certificates were not stamped in that year. It was filed with the registrar in El Paso—in Hamilton County on September 3, 1925, as shown by the date in the lower left hand corner of the certificate.

Q.—Well, the original certificate is part of the files and records of your office at the present time, is that right, Doctor? A.—It is.

Mr. Reynolds:—That was offered in evidence, with leave to substitute a photostatic copy.

Mr. Quaid:—We offer cross interrogatories to Dr. Davis of Austin, Texas.

Third Cross Interrogatory:—State the number of deaths from tuberculosis, during the period of time asked for information from you in the direct interrogatories, that were reported by the following named institutions and doctors in El Paso: Dr. J. W. Laws. A.—It is an impossibility for me to give any idea whatever—

Mr. Reynolds:—Your Honor, these answers are not harmful at all, but it has no relevancy. I suggest where it has not been asked on direct examination we omit it. I object to that question.

Judge Sweeney:—He says he does not know.

Mr. Reynolds:—That is all right, I just wanted to save some time.

The Court:—Yes, it appears to the Court you should eliminate it if it is not material. Very well, you may proceed.

Tenth Cross Interrogatory:—State, as a physician, how you or any other physician could arrive at a definite, final and correct conclusion with reference to the efficacy of any medicine administered to a human being, outside of analysis showing the medicine to contain elements which would be poisonous or detrimental.

Judge Sweeney:—That was objected to, Mr. Harrell.

Mr. Reynolds:—Yes, I will object to that because this man was not asked about this; he is just the Registrar of Vital Statistics.

The Court:—The Court will sustain the exception.

Mr. Reynolds:—Now, at this time, we wish to introduce and read in evidence another testimonial from the El Paso Times of Sunday, August 10, 1924, the full page advertisement already admitted as Defendant's Exhibit 14. The title is "Shadows of the 'Dark Ages' Still Cast Their Pall."

(Reading):

Little Rock, Ark., Aug. 6, 1923.

Dr. Asa Brunson,
Little Rock, Ark.

Dear Doctor:

I do not think it is possible for me to overstate the great value of the Dr. Asa Brunson Treatment for Tuberculosis. My wife, Mrs. Carrie E. Whitney, was in a precarious condition only a year ago, and I had no hope for her recovery or living to see 1923. Dr. Brunson's treatment has made it possible not only for her to live, but to live in her home, where life is worth living to most people.

C. E. Whitney, M.D.

Mr. Reynolds:—I also wish to read in evidence a short paragraph from Defendant's Exhibit 13, El Paso Times for June 19, 1921, which has been referred to in this case as the Griffin article.

(Reading): "Mrs. Edgar Blackwell of Pine Bluff, wife of a cotton planter, wires: 'Regarding my experience with the Holderness treatment for tuberculosis I cannot express my confidence in it too highly. I was bedfast after having suffered for thirteen years since my first hemorrhage. Today I am feeling fine, sleep well, eat heartily and am enjoying life. I bless the day Dr. J. S. Holderness entered my life. I am improving daily.'"

Mr. Reynolds:—Now, at this time we wish to read the deposition of Mrs. Katherine Ellis Wiles, of Little Rock, taken in Little Rock, Arkansas, on the 8th day of May, 1939.

DEPOSITION OF MRS. KATHERINE ELLIS WILES: DIRECT EXAMINATION

Questions by Mr. Harrell:

Mrs. Wiles, Little Rock, stated that she was chief clerk of the Bureau of Vital Statistics, State Board of Health, for the State of Arkansas. The name of her superior is Mrs. J. B. Collier, Director. The state registrar is Dr. W. B. Grayson, by virtue of his office as state health officer.

Q.—Tell us, in a general way, what work you do there, Mrs. Wiles. A.—The first thing I do in the morning, I open the mail and handle all the mail that comes in the Bureau of Vital Statistics; and the reports are classified by me. I handle all birth and death certificates from the time they enter the office until they are bound in volumes, indexed, transcribed and so forth. These are my principal duties.

Q.—I will ask you— A.—The others are various. I couldn't tell you all I do.

Q.—do you have charge of the files, of the records of the bureau of vital statistics, which contain certificates made by physicians of persons who are deceased? A.—Well, I wouldn't say I have charge of them. I am in the office and have access to them. I handle them from the time they come into the office and until they are bound in book volumes and put on the shelves. Then I wait on the public and so forth, but I am not officially in charge of the records.

Q.—I will ask you if you have in your files the original death certificate of Mrs. Carrie Egbert Whitney? A.—Yes, sir—I remember that distinctly.

Q.—I show you a certified copy of the death certificate of Mrs. Carrie Egbert Whitney, which has been marked Defendant's Exhibit A of this date, and ask you if that is a true and correct copy of the original death certificate as it appears in the files of the Bureau of Vital Statistics of the State of Arkansas (handing the paper to the witness)? A.—It is.

Q.—I will ask you if your records contain the original death certificate of one Fay Blackwell? A.—They do.

Q.—I show you a certified copy of the death certificate of Fay Blackwell and ask you if that is a true and correct copy of the original death certificate of Fay Blackwell as it appears from the files and records of the Bureau of Vital Statistics of the State Board of Health of Arkansas (handing the paper to the witness)? A.—It is. I knew that woman.

Q.—You knew her? A.—Uh-huh.

Q.—I will ask you if your files and records show or contain the original death certificate of Sister Rosalie Bradley? A.—They do.

Q.—I show you a copy of the original death certificate—certified copy of the original death certificate of Sister Rosalie Bradley, which has been marked "Defendant's Exhibit D" for identification, and ask you if that is a true and correct copy of the original death certificate as it appears in the files and records of the Bureau of Vital Statistics of the State of Arkansas? (handing the paper to the witness). A.—It is.

Mr. Reynolds:—I now offer in evidence the death certificates in the deposition of Dr. W. A. Davis, which have been identified respectively as Defendant's Exhibits 20 to 24, the same being the death certificates of George B. Hurst, Vassie Aulds, Anna Marie Hale, Margaret Holliday Clark and William Terry Bolding. At this time I will just read the jury short parts of them. Death certificate of George B. Hurst, signed by Ralph H. Homan, El Paso, Texas, filed the 10th day of May, 1939; date of death June 18, 1934, cause of death pulmonary tuberculosis, tuberculous meningitis.

Death certificate of Vassie Aulds, showing date of death December 19, 1933, cause of death, pulmonary tuberculosis, tuberculous peritonitis, contributory causes of importance, tuberculous meningitis.

Death certificate of Anna Marie Hale, date of death April 4, 1934, cause of death acute pyelitis, contributory causes of importance, tuberculosis.

Death certificate of Margaret Holliday Clark, date of death December 29, 1921, cause of death ulcerative phthisis.

Death certificate of William Terry Bolding, date of death August 5th, 1925, cause of death, pulmonary hemorrhage, contributory cause tuberculosis.

Mr. Reynolds:—I now offer in evidence death certificates attached in the deposition of Mrs. Katherine Ellis Wiles, from the Department of Vital Statistics of the State of Arkansas.

Death certificate of Mrs. Carrie Egbert Whitney, Fay Blackwell, and Sister Rosalie Bradley. Which have been marked Defendant's Exhibits 25 to 27, inclusive, respectively.

Mr. Quaid:—No objection.

Mr. Reynolds:—And ask leave to read to the jury short parts.

Mrs. Carrie Egbert Whitney, 521 North Pine Street. Date of death August 24th, 1930; cause of death, tuberculosis chr. fibrous, chr. standing for chronic.

Death certificate of Fay Blackwell, Pine Bluff, 318 West 15th. Date of death August 4, 1928, cause of death fibroid phthisis.

Death certificate of Sister Rosalie Bradley, date of death May 16, 1923, cause of death, pulmonary tuberculosis. Signed Asa Brunson.

Said death certificates were then received in evidence, marked "D-20" to "D-27", inclusive.

TESTIMONY OF DR. HARRY JOHN CORPER: DIRECT EXAMINATION

By Mr. Reynolds:

Harry John Corper, Denver, stated that he is a physician and research investigator. He received his collegiate degree at the University of Chicago as bachelor of science, Ph.D. at the Ogden Graduate College, that was in chemical pathology and M.D. at Rush Medical College. He is a member of the National Tuberculosis Association, the American Society of Clinical Pathologists, the American Medical Association, the American Society of Bacteriologists and Pathologists, the American Chemical Society, of course, the Colorado Tuberculosis Society, County Medical Society of Denver, and the Colorado State Medical Society. He has been president of

the American Society of Clinical Pathologists, secretary-treasurer of the same society; twice chairman of the Pathological Section of the National Tuberculosis Association; at present treasurer of the Colorado Tuberculosis Society and director of the Denver Tuberculosis Society. He was a member of the Illinois Industrial Disease Commission with Dr. Emory R. Hayhurst, now at the Ohio State University and with Alice Hamilton and under the supervision of Dr. Hektoen; also a representative to the national association from the local society. He is on the advisory board of the Colorado State Tuberculosis Section of the Welfare Section and director of research at the National Jewish Hospital, which is a non-sectarian institution, and assistant professor of medicine at the University of Colorado School of Medicine. He taught at the University of Chicago in pathology and in chemistry; in the University of Illinois, at Urbana, Ill., in physiology, then doing service during the World War under Colonel George Bushnell in the school for tuberculosis for the officers in tuberculosis at New Haven, Conn., and affiliated with the University of Colorado School of Medicine, in which he has been assistant professor of medicine since 1925. He is director of research at the National Jewish Hospital. Formerly, at the time of its inception and for a number of years he was director of research and laboratory of the City of Chicago Municipal Sanitarium. During army service he was director of teaching and director of research and laboratory of the government service and was associated with Dr. Milton Winternity, dean of the Harvard School of Medicine.

Q.—Were there any other schools for teaching the subject of tuberculosis at that time pertaining to the army? A.—No, sir, that was the original and the only school in which the army conducted its teaching of tuberculosis.

Q.—Do you know whether or not Dr. Asa Brunson was a student and enrolled at that particular school? A.—No, sir, he was not, because we have a complete roster of the members and his name was never on the roster.

Q.—Will you tell us if you have held or do hold any positions of an editorial nature? A.—Yes, sir. I am associate editor of the *American Review of Tuberculosis*, which I have held for many years, back practically since its inception in 1917, and I am editor of the *American Academy Bulletin of Tuberculosis*, besides some positions I hold with the American Chemical Society, and the *Archives of Pathology*.

Q.—Will you tell us in a general way whether you have done any writing on the subjects of pathology or tuberculosis during your practice? A.—Yes, sir, beginning about 1910 I have written an average of four to eight articles a year, and my number of articles are totaling in the hundreds now, that is original scientific, signed articles.

Q.—Have you been the editor or author of any medical books? A.—Yes, we have a Volume of Contributions to Tuberculosis, which has thirteen numbers, which was started in 1919, of which I am the editor.

Q.—With what hospitals have you previously been connected which you have not mentioned? A.—There is one hospital I am connected with I forgot to mention, and that is my association with Fitzsimons General Hospital, which is right in our vicinity in Denver, and I am associated with this as lecturer to the medical officers of this hospital.

Q.—That is a United States Army Hospital? A.—The largest United States Army Tuberculosis Hospital.

Q.—Do you hold a commission in the United States army? A.—Not at the present time, but I was major in the Medical Corps in the army in the World War and continued as major in the reserves in the United States army until 1930.

Q.—Dr. Corper, have you received any honors, medals, certificates or awards for contributions to science? A.—I think we can include in that membership in Phi Beta Kappa, which is the academic honorary collegiate society, to which I was elected on the basis of scholarship. Besides I am a member of Sigma Xi honorary society, which is awarded on the basis of scholarship. I am a member of Alpha Omega Alpha, which is also based on scholarship. I received the gold medal for scientific work for the American Society of Clinical Pathologists. I received a medal from the American Medical Association for an exhibit and I received honorary scientific mention from the American Medical Association.

Q.—Do you follow a specialty at the present time? A.—Yes, sir, my specialty is tuberculosis, particularly stressing the investigative and pathologic sides.

Q.—Will you tell us in a general way what the nature of your work is? A.—My time is practically all spent at investigative work. I might also say I have been accepted as a specialist

by the Board of Internal Medicine and by the Board of Clinical Pathology in the fields both of clinical tuberculosis and pathological anatomy.

Q.—Dr. Corper, I am now showing you Defendant's Exhibit No. 20, which is the death certificate introduced in evidence and listing the cause of death. I wonder if you would explain just what that means? A.—It says pulmonary tuberculosis, 1922, as a primary cause and tuberculosis meningitis as contributing cause. That means that the individual died of tuberculosis not of any secondary infection, and the individual during the course of this had a tuberculous meningitis, which probably was the final lethal condition.

Q.—And that is the certificate of George E. Hurst to which you are referring? A.—Yes, George E. Hurst.

Q.—Exhibit No. 21, certificate of Vassie Aulds, I hand that to you and ask you to explain from what cause she died so we may understand it? A.—This patient died of the important cause of pulmonary tuberculosis and tuberculous peritonitis. That means the individual had enough tuberculous disease in the lung as well as in the peritoneum, which is a covering of the intestines in the abdomen.

Q.—I will show you now Defendant's Exhibit No. 22, the death certificate of Anna Marie Hale, and ask you to explain what is listed there and was the means and cause of death. A.—The cause of death given here is acute pyelitis, which merely means the condition of the kidneys and does not state the cause of organism. It may be of any type or other. We can have acute pyelitis caused by acute germs and micro-organisms as well as tuberculosis. Then there is another contributing cause given, tuberculosis, which is perfectly obvious as a disease caused by the tubercle bacillus.

Q.—Doctor, on the death certificate of Margaret Holliday Clark, Defendant's Exhibit No. 23, will you read and explain to the jury what the cause of death was? A.—This is designated as chronic ulcerative phthisis. Now there are a number of names for consumption or pulmonary tuberculosis and phthisis happens to be one of these terms. Phthisis merely means that this individual has had pulmonary tuberculosis or consumption and it was of a chronic ulcerative type. By the ulcerative type we mean this individual had probably had excavations in the lung or ulcer, as we might designate them, and it was chronic, of long duration.

Q.—Incidentally have you ever seen those death certificates before? A.—Yes.

Q.—I show you now Defendant's Exhibit No. 25, the death certificate of Mrs. Carrie Egbert Whitney, with the cause of death and abbreviations there. Will you explain to the jury what it stands for? A.—This says tuberculosis chr., which stands for chronic. It says fibrous, that means that the individual had tuberculosis, died of it, it was a chronic, slowly progressive type and that it was fibrous, there was a predominance of fibrous or scar tissue in that individual.

Q.—I now refer you to Defendant's Exhibit No. 26, death certificate of Fay Blackwell, and ask you to tell from what she died, according to that certificate. A.—This person died of fibroid phthisis. That means the individual had pulmonary tuberculosis of the fibroid or scar tissue type. Scar tissue, of course, being the type we see in all scars, as we in the medical profession know it, being made predominately of connective tissues.

Q.—I show you Defendant's Exhibit No. 27, Sister Rosalie Bradley. A.—That is pulmonary tuberculosis. I think that is clear.

Q.—Now, Dr. Corper, how long have you been specializing in tuberculosis and especially in research in pathology? A.—Over twenty years.

Q.—In connection with your work, do you grow the tubercle bacilli? A.—I grow them for my experimental studies in large amounts, and possibly at the present time in my own laboratory I must have pounds and pounds of them.

Q.—Dr. Corper, is it a common opinion of the best doctors today that every one has tubercle bacilli in their system? A.—This it not the accepted opinion today. It is an opinion that dates back to some erroneous observations in the early part of the century, about 1900, when Dr. Naegeli by means of tuberculosis tests in big cities found a high percentage of the population positive to the test. He therefore deduced from that, because in a city like Vienna there was a high percentage of positive tests, that everybody had tuberculosis. With reinvestigation of this subject, especially in this country and other countries of this type, we found out this is not true. In a state like Minnesota we do not have more than 10 per cent of the population being infected by the tubercle bacilli during the period of their life.

Q.—Doctor, what creates tuberculosis? A.—The causative agent of tuberculosis is the tubercle bacillus, the specific cause.

Q.—Have you ever seen tuberculosis created? A.—Yes, sir, very many times. I have produced it many times in animals. As a matter of fact I produce it on an average of hundreds of thousands of times annually.

Q.—Now, Doctor, without a mixed infection would tubercle bacilli ever do much harm? A.—Yes, sir, the tubercle bacillus can kill an individual without any mixed infection. Also tubercle bacilli can produce a range of reactions which resemble acute reactions, which you heard me recite in some of those cases, such as fibrosis.

Q.—Have you ever experimentally seen this happen? A.—Yes, sir, we can reproduce it at any time. It is merely a matter of the number of bacilli concentrated in one point; if the bacilli are numerous or highly virulent they produce an acute type of reaction and the reaction there is the influx of acute phagocytic blood cells, acute pus cells.

Q.—Have you ever produced death as a result of the tubercle bacilli, without having accompanying it any mixed infection? A.—Yes, sir, it can be done regularly.

Q.—You have never done it on humans, only on animals. A.—It has been done on humans. There is reported a case of a young fellow accidentally inoculating himself in Paris intravenously, where mixed infection played no part and he died from that inoculation.

Q.—Doctor, in your opinion is it or is it not a fact that a doctor or chemist cannot arrive at a positive conclusion without trying out a medicine? A.—Will you repeat that.

Q.—Doctor, in your opinion is it or is it not a fact that a doctor or chemist cannot arrive at a positive conclusion without trying out a medicine? A.—I do not believe that any one can arrive at a positive conclusion regarding any therapeutic agent without thorough and careful trial.

Q.—Does that mean that it has to be tried on a patient when administering a medicine that is advanced? A.—I personally do not contribute to experimentation on patients with anything that may be a trial and which may result in any type of injury.

Q.—Now, Doctor, if you know the nature of the ingredients of a particular medicine, their physical or chemical composition, the properties, is it necessary to try them out on an individual before determining whether or not they have any efficacy? A.—I think it would be better to put it this way. It would be wiser to try these medicines out on experimental animals to try their efficacy before in any way applying them to a human being. I would like to elaborate on that, and say wherever these materials have been tried on a human being we have a number of classic examples in which human beings have been definitely injured by such trial.

Q.—Do you know whether or not the use of volatile oils in tuberculosis has ever been so tried? A.—Not in a satisfactory manner to my knowledge. Only from the standpoint of the injury that might be produced. These volatile oils might have a definite injurious effect.

Q.—By that you mean it has been tried by some and the results are unfavorable? A.—The results are unfavorable in that they are injurious.

Q.—Now, Doctor, after a body has been embalmed, is it impossible to see tubercle bacilli at an autopsy through a microscope? A.—Not at all if we stain them properly. They can be seen even when they are dead, when you cook them, when you embalm the body and when you treat them with many chemicals, that is, chemical reagents. They are resistant to many chemical reagents, they are a very hardy organism.

Q.—Now, Doctor, will you describe a tubercle for us. A.—By a tubercle, of course, we mean a classic picture which does not aptly describe what we see in the tuberculosis. The classic tubercle—the word tubercle means a little nodule. Now, we can have tuberculosis without having these classic little nodules and we have them in various forms and various types. The classic tubercle does not usually include the acute reactions which occur in what we call exudative reaction. Therefore the classic tubercle in itself, which is a reaction in the body to tubercle bacilli, is not the only index of tuberculosis.

Q.—Doctor, in connection with pulmonary tuberculosis is the mucus—is it mucus that we usually call pus? A.—No, sir, the mucus is not the pus. Even when we look at the sputum we characterize the sputums in at least three ways. We characterize it mucoid because there is a lot of mucus and mucous secretion in the cells, and we characterize it purulent because there is a lot of pus, and we characterize it mummular or caseous because there is a lot of so-called cheesy material from chronic types of tuberculosis, where the tissues have died and left this cheesy material.

Q.—Doctor, has it ever been definitely established that a pus germ has caused every symptom that is manifested in the disease of tuberculosis? A.—No, sir, I investigated this myself in 1918 and on the basis of my own work I can say it is not. The pus germ, as we understand, plays very little part in the tuberculosis. At that time there was a conception that this germ by getting into the blood would cause a fever and symptoms of tuberculosis. Today we know that is not true. The pus germ does not play any part in the symptoms of tuberculosis.

Q.—How long did it take you to make that study and come to that conclusion? A.—It took about four years.

Q.—Have you ever seen under a microscope a specimen of sputum from a tuberculous patient in which specimen pus germs did not predominate? A.—Yes, sir, we frequently have specimens which are almost pure cultures of tubercle bacilli except for some of the cells that may be there. They are easily seen, they are little red rods, we stain them red.

Q.—Now, Dr. Corper, is it true that, in pulmonary tuberculosis, disease may be accompanied by cough and increased temperature or, in other words, fever, increased pulse rate and lowered blood pressure? Is that true? A.—Yes.

Q.—When a person has those four symptoms do they necessarily have tuberculosis? A.—No, sir, there are many other diseases that can imitate those symptoms and give them to us without the presence of tuberculosis.

Q.—In regard to these many diseases may they be treated by the same methods as are recommended as a treatment for tuberculosis? A.—No, sir, entirely different.

Q.—Doctor, assume a case of suspected tuberculosis of the larynx. Assume that a doctor accumulates some of the mucus in the larynx and puts it under a microscope. In your opinion is that all that is necessary to diagnose tuberculosis of the larynx. A.—No, sir.

Q.—What else should be done, must be done? A.—A direct examination at least should be done, and, of course, then this should be verified by a complete examination of the individual, because usually the larynx or vocal cord tuberculosis is secondary to pulmonary and there are so many conditions that might imitate tuberculosis of the larynx that we have to be very careful and rule them out.

Q.—Now, Dr. Corper, in connection with silicosis, will you tell the jury first what silicosis is? A.—Silicosis is a condition usually in the lungs, resulting from the irritation produced by a silicious or silicate type of inhaled dust.

Q.—Now, in silicosis is it necessary to have mixed infection before there are rales? A.—No, sir, we can have rales without mixed infection. A rale is merely an index of moisture being present there and whenever there is irritation we can have moisture which will give the rales.

Q.—Will you explain to the Court and jury, Doctor, just the meaning of fibrosis? A.—In the simplest way fibrosis merely means the influx of cells that we call fibroblasts, which then accumulate to form fibrous or scar tissue. I think you have all seen scar tissue and you know what it is like. I have a scar on my thumb and I think most of you have.

Q.—Is that the same definition as for fibrin? A.—No, fibrin is the clotting constituent in the blood and has nothing whatever to do with fibrosis. Fibrin is not a cellular material, it is a humoral material.

Q.—Is it more difficult to diagnose an apparently cured pulmonary tuberculosis than it is a lack of cure? A.—Yes, sir, I should say so.

Q.—Is it possible in your opinion to discharge as apparently cured a patient who had suffered with pulmonary tuberculosis without making any sputum tests or any x-ray plates of his lungs? A.—It is impossible.

Q.—In the treatment of tuberculosis, Doctor, is it good practice to allow a patient to be up and out of bed while he is running a temperature or fever? A.—No, sir, it is absolutely urgent that the individual be in bed with a fever.

Q.—As a matter of fact is there any disease or dysfunction in which that is a good practice known to medicine? A.—It is a bad practice to be up with fever.

Q.—Is there any difference in fever and above normal temperature? A.—Not that we recognize. It means the same thing.

Q.—Now, Dr. Corper, I want you to assume a hypothetical treatment for pulmonary tuberculosis, in which there is an inhalation of an oily vapor that is produced by the use of an atomizer or nebulizer to which is attached an oxygen tank, that the pressure gage on the oxygen tank is set at about 35 to 40 pounds, that the bulb of the atomizer contains oily substances composed essentially of 95 per cent mineral oil and approximately 5 per cent volatile terpene-like substance of steam

distillable like oil of eucalyptus and menthol, sometimes called mint camphor, and terpene-like substances resembling oil of pine and thymol, that the tip of the atomizer is inserted in the patient's mouth and he is required to inhale ten times, that this treatment is administered twice daily, have you an opinion based on reasonable medical and scientific certainty as to whether or not such a treatment could or might be efficacious in the treatment of tuberculosis, pulmonary tuberculosis? A.—I think we can say—

Q.—Doctor, just answer if you have an opinion. A.—Yes.

Q.—What is your opinion? A.—My opinion is that with the best of our knowledge today we do not know from all scientific information available that such treatment is beneficial. It has another factor in it, it may be harmful.

Q.—Do you have any scientific knowledge today on which to base the opinion it might be harmful? A.—Yes, sir.

Q.—Will you explain that? A.—I would like to elaborate on this: In the first place that the pressure on any gage when the vaporizer or the atomizer is held in the mouth is no index of the pressure at which that comes into the mouth. In the second place, we are fortunately protected by nature in the fact that materials that get into the mouth are not easily transmitted into the lower parts of the lung. Now, even with our breathing, materials may enter the larger tubes, the bronchi and trachea of the lung but they do not go very far for the simple reason they go only so far as the tidal air carries them. We do not exchange the air in the lung with every breath. In addition to that we have a protective mechanism of the trachea and bronchi in having little cilia on which these materials lodge in the larger tubes and which are intended to carry them up. That is what we see in the morning in a smoky city in the form of soot; it is a protective mechanism. Now, the most vital part of the lung is a little air sac or alveolus and the only way material can get into that is by means of what we call aspiration. If we have sufficient liquid there or accumulation of material and it once gets into the air sac usually very mild substances like liquid petrolatum or ordinary petroleum oils may produce a decided irritation and throw these alveoli out of function.

Q.—Doctor, what is the effect of oxygen on a tubercle bacillus? A.—The tubercle bacillus is what we call from a bacteriologic standpoint an aerobe. That means the tubercle bacillus likes oxygen. There are other organisms that prefer to be away from oxygen. We call them anaerobes. Now, the tubercle bacillus also has a tremendous latitude for obtaining this oxygen and it will take oxygen away from other cells when it is there even in small amounts. Now the fact that the tubercle bacillus is an aerobe is demonstrated when you grow liquid cultures of this organism. You will always find the growth on the surface of the liquid, not in the bottom of the liquid.

Q.—Doctor, in regard to this hypothetical treatment to which we have been referring, have you an opinion as to whether or not such a treatment is dangerous to a patient having pulmonary tuberculosis? A.—Yes, sir, it can be dangerous. It can produce a bronchopneumonia, very much resembling tuberculosis, because it is the waxy and fatty materials in the tubercle bacilli that produce the tubercle so called, and these oils have a close resemblance in that respect to the tubercle bacillus.

Q.—Now, Doctor, if we should change the oily substance in the bulb of the atomizer that was referred to in the hypothetical question and substitute instead an oil consisting essentially of from 95 to 96 per cent light mineral oil, 3 to 3½ per cent, more or less, oil of eucalyptus, and 1 to 1½ per cent menthol, no other substances, would your answer be any different regarding the efficacy of it as a treatment? A.—Not at all. That group of terpenes are all toxic and as a therapeutic method these materials do not enter the disease focus of tuberculosis and cannot have any effect on the tubercle bacillus.

Q.—Now, Doctor, if we should change the composition of that oily substance and say that the treatment involved the inhalation of eucalyptol, menthol and turpentine, would your answer as regarding its efficacy and danger be different in any respect? A.—No, turpentine was a little more caustic and would be a little more detrimental. Still they are all detrimental.

Q.—All these groups of oils, Doctor, that we have mentioned in the terpenes would it make any difference so far as the efficacy of such a treatment for pulmonary tuberculosis is concerned in what proportion or percentage they might be juggled? A.—I do not think it would make any difference.

Q.—Your conclusion is that they are all essentially the same? A.—Essentially the same.

Q.—Doctor, there has been a lot of talk, now, about terpenes here, will you explain to the Court and jury what is meant by that term? A.—Terpene is a chemical radical, and this consists

BRUNSON VS. FISHBEIN

313

of a certain ring group with a chain group, which has probably been explained to you before, and in that group we have these compounds which are of the aromatic series, as we call them. They are aromatic oils, and they are of a certain constitution and they all have certain common properties; among those properties is the factor that they are irritants and deaden certain nerve endings.

Q.—Now, Doctor, in connection with the use of oils and their effect on the lungs, have you done any special work in that field? A.—Yes, sir, I have written on that, on such inert oil as liquid petrolatum, that is supposedly inert.

Q.—That is the same as mineral oil? A.—Liquid petrolatum, olive oil, and the famous chaulmoogra oil. I didn't publish my work on the terpenes because I never found any results that were encouraging at all; the detrimental features outweighed the beneficial.

Q.—Doctor, in connection with your work on oils, how much time have you devoted to that? A.—I published a number of articles in 1922, and I have been interested in it for years; I can't state the exact number of years.

Q.—Now, Doctor, if—well, first, have the various constituents of these oils we have described to you here been tried out scientifically? A.—Yes, sir.

Q.—You know that to be a fact? A.—Yes, sir.

Q.—And if given one of these particular oily solutions, is it necessary for you to try it on a patient now in order to determine whether it is efficacious or not? A.—No, sir.

Q.—In connection with your work on oils, Doctor, will you describe to the Court and jury just what some of the various types of experiments are in their nature? A.—When we do an experiment in tuberculosis, the first problem that we approach is a problem of whether this material can be placed where it is supposed to affect the germ of the disease. Now, when we apply these oils as they are applied here, by inhalation, even if we forced them into the lung, they could not possibly come to the disease focus. They could not get near the tubercle bacillus because the tubercle bacillus is in a walled off area and it is thoroughly protected against the oil; it is in a walled off area in every respect to any of these drugs, and you must remember we have no specific drug today for tuberculosis, and the reason for it is these cells are much more sensitive, and the lung cells are much more sensitive, than the tubercle bacillus itself. Then the tubercle bacillus is an extremely hardy organism; we can place him under the most exacting condition and he still survives. He survives in places where the ordinary animal of any type cannot possibly survive. You can put him into liquid air, which is extremely cold; it would burn a human being, freeze him, rather, we call it burn; you can put him in liquid helium, it is so cold a chemist puts it as close to absolute zero, and the best drying agents the chemist knows of, as a matter of fact, that is one of the ways we preserve him; we keep him in the laboratory in a sealed tube after he has been dried, and put him in the icebox and he keeps alive and better than under other conditions. We can do a great many other things to him; that is how he is hardy, an extremely hardy organism.

Q.—Have you conducted all these experiments yourself? A.—Yes, sir.

Q.—Generally, in experimenting with oils, Doctor, you have found what you found out, but will you tell us just a few experiments that were carried on to come to your conclusion in your work? A.—You see tuberculosis is a primary disease, in which the bacillus is protected; we cannot approach that through the lung because we run into the difficulties I explained.

Q.—How did you find it out? A.—By actual experiment and analysis.

Q.—Of what? A.—For instance, by analyzing the materials used, analyze them in the tubercles, and try to find if they even enter; they do not enter, any more than oil mixes with water, and you must remember that the cell itself is primarily not an oily organism but water organism. If we fail, the best approach, from the standpoint of protection, would be by intravenous injection, and it is perfectly obvious these oils cannot be injected into the blood.

Q.—Have you tried those on human beings? A.—No, sir.

Q.—How did you try that? A.—Experimental animals. We can examine animals microscopically; examine by chemical examination and by gross examination, so we can see exactly where the materials go to.

Q.—Have you tried with all these oily substances similar to what we have been talking about? A.—Yes, sir.

Q.—Have you studied the effects of oils on the lungs at postmortems? A.—Yes, sir. In human beings?

Q.—Yes. A.—Yes, sir.

Q.—Approximately how many, would you say? A.—Well, in my period, I have seen, well, I should say over twenty cases in which oils were involved.

Q.—Now, Doctor, is there any similarity between the action of oils on the human lung, discovered in postmortems, and the action of the tubercle bacilli themselves? A.—Yes, sir, there is very striking similarity, because these oils, when they enter these little trees of the lungs, little air spaces, produce a bronchopneumonia, and the bronchopneumonia resembles very much the naturally occurs in man when his disease spreads.

Q.—Have you prepared specimens for illustrating that? A.—Yes, sir.

Q.—I show you now a specimen (gross specimen of lung in a jar) that has a pencil mark "F-3" on it and ask you to state if you have seen it before? A.—Yes, sir.

Q.—Explain to the Court and jury what this is. A.—This is a case of tuberculous involvement of the lung; it is shown here by the lighter areas; we call it the bronchiogenic spread type, it is not the fibrous type; it is the acute type more or less, and in medical terminology we call it the acinous type of tuberculous pneumonia.

Q.—That is part of the human lung, is it? (Referring to specimen.) A.—Yes, sir.

Q.—I will ask you to look at another specimen marked "CA-203" on it and tell us if you have seen it before. A.—Yes, sir, this is a specimen from a man who aspirated an oily material, trachea from his mouth; it went into the finer divisions of the lungs and produced bronchopneumonia; this bronchopneumonia is of the same type we have in this case; that is tuberculous. That is "F-3." Here we have a lipid or oily bronchopneumonia in this specimen.

Q.—You say you have seen those specimens before. Where? A.—I put them up and brought them along.

Q.—You prepared them? A.—Yes, sir.

Q.—Now, as regards these two specimens, this on my right is which? A.—That is lipid pneumonia and that is tuberculous bronchopneumonia (indicating); lipid bronchopneumonia and tuberculous bronchopneumonia.

Q.—Doctor, will you point out what on those two exhibits or specimens, that is distinguishable to the human eye, indicates a pathologic similarity between the two conditions? A.—Well, if you look at these specimens you see the thing that is similar here is the injury to the tissues, which is shown by the lighter areas and which is designated by the doctor as bronchopneumonia because this material has entered here the lighter divisions down to the alveoli, little air sacs, and gives you this picture, which very much resembles tuberculosis because both of them were produced the same way, by aspiration of irritating material into the human lung tissue.

Q.—I notice that the general background of color in these two specimens is a little different; has that any pathologic significance? A.—No significance at all; because sometimes a lung will be prepared in a little darker fashion. The average doctor would have a great deal of difficulty in differentiating these two conditions.

Q.—As a matter of fact, between two different individuals, the appearance of the lung is different, when actually seen? A.—In different parts of the lung.

Mr. Reynolds:—I would like to pass these to the jury.

The Court:—I think they can be explained, possibly by the witness by holding them up before the jury, more satisfactorily.

Mr. Reynolds:—I think that has been done.

The Court:—Than to pass them around among the jurors, and they can draw their own conclusions, that would be more satisfactory to the Court.

Mr. Reynolds:—If the Court please, may I have Dr. Corper step closer to the jury and explain this to them.

The Court:—That will be satisfactory to the Court.

Q.—Will you explain to the jury, Doctor, the pathologic similarity between these two specimens and give the account of the cause? A.—This specimen we call lipid or oily pneumonia. These are the larger blood vessels and larger bronchi. These dark areas are normal air-containing lung tissue. The areas here that are paler are the little so-called bronchopneumonia, these little patches that are lighter. You notice they are in the form of a pulmonary tree, as we call it, in the form of the lung itself and air passages. Frequently we use the term air cells, that is wrong, not air cells, they are air sacs, little holes, which are elastic, in which the irritating material can

float; they are innumerable, some little and some large. You see the striking similarity between the oily pneumonia and the tuberculous here, which is caused by the tubercle bacillus. It is perfectly obvious things that go in the same place, if they irritate at all, must resemble each other. It is absolutely impossible to tell these conditions apart unless you examine for the materials in them—in this case the tubercle bacilli.

Q.—What is this type? A.—This was the aspiration of milk.

Q.—What is that? A.—It produces exactly the same effect whether the oily fat of the milk or whether it is the fact of the tubercle bacillus.

Q.—As far as the symptoms are concerned, is there a similarity or not? A.—Yes. This individual may show no symptomatology or pathology.

Q.—As far as the two are concerned, could you tell the difference by the four things we listed, temperature, pulse, blood— A.—No.

Q.—Now, Doctor, are you acquainted with Dr. Morris Fishbein, the defendant in this suit? A.—Yes, sir.

Q.—Do you know his general reputation as a medical man? A.—Yes, sir.

Q.—Will you tell us what it is, please? A.—Well, I have known Dr. Fishbein for a great many years; I know him to be absolutely honest, sincere; I have personally given him the nickname of "Defender of mankind and medicine." My reason for that is his grounding in pathology—he knows about pathology; his grounding in scientific and investigative medicine is sufficient to make his statements absolutely reliable. I would like to say one other thing and that is the fact that, in all my years of acquaintance with Dr. Fishbein, I have never known him to even harm a mosquito unless it became necessary to do so to protect—

Mr. Quaid:—I object to that argument.

The Court:—Sustain the exception.

Q.—Doctor, do you know whether or not Dr. Fishbein enjoys that reputation generally in the field of medicine and surgery? A.—Yes, sir, I think, among the reputable medical profession and among the educators Dr. Fishbein is a very able educator; among educators he enjoys that reputation.

Q.—Doctor, how long have you known Dr. Fishbein? A.—For thirty years.

Q.—Did you ever study with him? A.—Yes, sir.

Q.—Will you tell us when and where and under what circumstances? A.—I studied with him in school, I was a classmate of his; I studied with him in the McCormick Institute for Infectious Diseases when he was doing pathology, and I have known him fairly well since.

Q.—Under whom? A.—Ludvig Hektoen, E. R. LeCount, Dr. Frank Billings and a number of others.

Q.—Doctor, what is a pathologist? A.—A pathologist is a man who has been especially educated and who understands the changes produced by disease in the tissues of man and animal.

Q.—And that is your specialty? A.—Yes, sir, I took my Ph.D.

Q.—Doctor, have you ever been certified to any board as a specialist? A.—Yes, sir, I have been certified as a specialist in internal medicine by the Board of Internal Medicine and by the Board of Clinical Pathology.

Q.—Doctor, do you know whether or not Dr. Fishbein is a pathologist by education? A.—Yes, sir.

CROSS EXAMINATION

Questions by Judge Swency:

Q.—You are from Denver? A.—Yes, sir.

Q.—When did you come to El Paso, Doctor? A.—I came to El Paso on Saturday night a week ago.

Q.—You have been here ever since? A.—Yes, sir.

Q.—At whose expense are you here, Doctor? A.—I am at my own expense.

Q.—You asked no remuneration and are expecting none? A.—I have asked none.

Q.—Do you expect any? A.—No, sir.

Q.—Now, Doctor, you have been staying at the Hilton Hotel, have you? A.—Yes, sir.

Q.—Are you paying your own expenses there? A.—Yes, sir.

Q.—You have met the other doctors, visiting doctors, from various places? A.—Yes, sir.

Q.—You discussed this case together, have you not? A.—Yes, sir.

Q.—You have been discussing it during this week, haven't you? A.—No, sir, not with the doctors. The last time I discussed the case with the doctors was on Sunday.

Q.—You all had a conference at that time, did you not? A.—Yes, sir.

Q.—Then you have eaten together, breakfast and lunch and dinner? A.—Yes, sir.

Q.—And you have incidentally discussed the case? A.—These men—I want to explain this, they are all personal friends of mine, of long standing, and some of them are pupils of mine.

Q.—Being doctors, you are all interested in this case? A.—Well, I don't know, except to present the facts.

Q.—I say, you are interested in the case? A.—That is what we came here for.

Q.—You naturally discuss those questions you are interested in? A.—No, we did not discuss this in any way outside of the conference I referred to on Sunday.

Q.—It was never mentioned among any of you since Sunday? A.—Incidentally, what we see mentioned in the newspapers might have been mentioned; we didn't make it our business to discuss this case.

Q.—So I understand you to say that since last Sunday you haven't discussed with anybody the questions of evidence in this case? A.—I didn't say that. I said I discussed probably incidentally, not specifically, what I might have read in the newspaper; I read the newspaper.

Q.—With whom did you discuss it? A.—I discussed it with Dr. Hruby—I don't say discussed, we just incidentally talked about it, I would rather use that term. With Dr. Hruby, who is a pupil of mine, Dr. Moorman, who is a friend of very long standing, with Dr. Watson, with Dr. Turner, and I think that is all.

Q.—That is all you incidentally talked to with reference to the case. You talked to Dr. Fishbein? A.—Not specifically, no.

Q.—You haven't incidentally talked about this case at all? A.—Not to Dr. Fishbein, no sir.

Q.—Doctor, you have written quite a number of articles on various matters with reference to medicine, on which you have been studying? A.—Not on matters, on scientific investigations.

Q.—On scientific investigations that you have made? A.—Yes, sir.

Q.—Those have been published? A.—Yes, sir.

Q.—And what papers have they been published in? A.—They have been published in both foreign and American journals, they have been published in the *American Review of Tuberculosis*, the *American Journal of Pathology*, the *Archives of Internal Medicine*, the *Journal of Laboratory and Clinical Medicine*, the *Journal of Biological Chemistry*, the *Bulletin of the American Academy of Tuberculosis Physicians*, the *Journal of Infectious Diseases*, and a number of others.

Q.—Practically all of those medical journals you have mentioned are connected more or less with the A. M. A., are they not? A.—Not a bit of it, they are entirely independent.

Q.—None of these publications are connected with or under the direction of Dr. Fishbein? A.—I didn't say that. Some of them are, yes, sir.

Q.—Which ones? A.—THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, the *Archives of Pathology*, and that is all.

Q.—Those two are connected with Dr. Fishbein? A.—Yes, sir.

Q.—And the A. M. A.? A.—Yes, sir.

Q.—Now, Doctor, you have been giving your close attention to the treatment of tuberculosis and its study since 1920? A.—No—

Q.—No, for twenty years? A.—I said since 1911.

Q.—Since 1911? A.—Yes, sir.

Q.—And you have been a tubercular specialist how long? A.—Since 1913. Now, I don't know what you mean by a tubercular specialist.

Q.—Didn't you answer to the direct interrogatories that you were a tubercular specialist? A.—Yes, sir.

Q.—That is what I mean. A.—What do you understand by a tubercular specialist?

Q.—I am not answering questions, I am asking them. A.—Excuse me.

Q.—You are a tubercular specialist? A.—Yes, sir.

Q.—And you have been for how long? A.—Well, in the broadest sense of the term, for at least twenty-eight years.

Q.—During the twenty-eight years, Doctor, how many patients have you had, tubercular patients? A.—You mean private or institutional?

Q.—Either one or the other? A.—Hundreds.

Q.—For illustration, how many? A.—Well, I should say that I had under my care some 650 at one time in the City of Chicago Municipal Tuberculosis Sanitarium; in the army we ran as high as 700 at one time; at the National Jewish Hospital we ran 250.

Q.—Now, the National Jewish Hospital you designated that as nonsectarian, what do you mean? A.—By that we mean that we are nonsectarian by the fact that we take all kinds of patients, regardless of creed or race.

Q.—Now, in your private practice, Doctor, during the last twenty-eight years, how many tubercular patients have you had? A.—None for pay.

Q.—It has just been in the nature of public work? A.—My services are all rendered free to private patients.

Q.—How many have you had? A.—I couldn't say they were very numerous, probably twenty.

Q.—In twenty-eight years? A.—Yes, sir.

Q.—And in twenty-eight years, you have had under your direction and control and administration, in all institutions, how many, the approximate total number? A.—I can't answer that because it runs way up in the thousands, and I have kept no accurate figures.

Q.—Among the twenty that you have had as private patients, how many did you effect a cure in? A.—I can't answer that.

Q.—How many died, Doctor? A.—I—

Mr. Reynolds:—I believe that is immaterial, Your Honor, because he has not gone into the conditions of the patients, the surrounding circumstances at all, he hasn't asked even of what they died, I object to it.

The Court:—The Court sustains the exception.

Q.—Did any of the twenty patients you administered to during the last twenty-eight years die of tuberculosis? A.—Not to my knowledge.

Q.—They did not? A.—No, sir.

Q.—Now, in the Chicago hospital and these other institutions you have had hundreds of patients under your direct administration. Do you know the percentage of those that were cured? A.—I can't give you the exact figure on that, because they are not cured according to the best medical terminology; they never cure a patient.

Q.—In the final analysis in your opinion there is no cure for tuberculosis? A.—I can't answer that because you do not define your term cured.

Q.—What does a cure mean, Doctor, in your language? A.—In my language there are two types of cures. A bacteriological cure is never attained. A tubercle bacillus can remain alive in the body for twenty-five years. A clinical cure can be achieved. That is an apparent cure, and the reason for that is because in all of the physical and pathological findings, and all these things we are concerned with, toxicity begins to disappear and subside, and the tubercle bacilli disappear from the sputum. We consider these cases apparently arrested; we do not call them cured.

Q.—You spoke a while ago of science and medical science. Is medicine a science? A.—Yes, sir.

Q.—Or is it an inexact, an incomplete science? A.—It would still be a science whether it was inexact—

The Court:—Read the question.
(The question was read.)

A.—May I explain that?

The Court:—Yes. You were starting to explain it before, were you not?

The Witness:—Yes, sir.

The Court:—Very well.

A.—Science, you see, goes by stages and sometimes by leaps and bounds. If medicine were a complete solved science, which is what I think you mean, we would not have any disease that we would have to combat. We must do our work in such a way that we find our faults and admit them and try to progress on that basis. In fact you call medicine a science, but medical science depends on all of the other sciences for progress.

Q.—Doctor, that is then what happened to Pasteur. He worked out a theory but he was ahead of his time, was he not? A.—No, I think you are misinformed on Pasteur. Pasteur

established facts which have benefited the world. He was not so much concerned with theories.

Q.—And he was criticized by practically all of the medical profession in the world? A.—That is not so.

Q.—That is not so, the medical profession supported him from the beginning? A.—As always with mankind, when there is a new progress in medicine there are groups of medical men who do not understand, who are skeptical and want to be shown. That is perfectly all right.

Q.—And Bodington in 1845, when he put forth the theory of rest and fresh air, what happened to him, Doctor? A.—I do not recollect anything, except that he did not get any patients.

Q.—He was criticized and put out of business by the medical profession? A.—No, sir, not by the profession at all. You are misinformed on that.

Q.—They criticized him, did they not? A.—I don't think so, not to the best of my knowledge.

Q.—He was severely criticized, was he not? A.—I don't believe so.

Q.—And the medical profession did not continue or follow his ideas? A.—Yes, sir.

Q.—Until 1870, when Dr. Brehmer of Vienna again took the theory up, is that not a fact? A.—I think you have some of those dates wrong, but Brehmer did take it up and it took Brehmer a long time in Germany, the Kaiser's country, to get permission to establish an institution; but you haven't the thing fully. Brehmer went to Bodington's idea after he, as a student, had gone to the postmortem table and seen some of these procedures, tuberculous conditions improve with rest and graduated exercise.

Q.—You were a fellow student, you say, with Dr. Fishbein? A.—Yes, sir.

Q.—An associate of his and have been ever since? A.—No, sir. I don't know what you mean by associate.

Q.—A friend? A.—Yes, sir, a friend.

Q.—Did you know Dr. Simmons? A.—I have met Dr. Simmons on occasions, yes, sir.

Q.—Were you and Fishbein protégés of Simmons and friends of his? A.—I think Dr. Fishbein was an employee of Dr. Simmons. I don't know whether you call an employee a friend. I can't answer that. Maybe Dr. Fishbein can answer that.

Q.—He was associated with him for a number of years? A.—In a business way, yes, sir.

Q.—As Assistant Editor of THE A. M. A. JOURNAL, was he not? A.—I think that is true.

Q.—And he succeeded Simmons about thirteen years after becoming his assistant? A.—I wouldn't say the exact years, but he did succeed Dr. Simmons.

Q.—You did not know Dr. Simmons yourself? A.—Yes, sir, I did. I had met Dr. Simmons, but I had no business dealings with him, or not a great deal of contact.

Q.—Just an acquaintance, that was all? A.—Yes, sir.

Q.—Dr. Simmons occupied the position with the A. M. A. that Dr. Fishbein now occupies, did he not?

Mr. Reynolds:—Just a moment, if Your Honor please. I do not think Dr. Simmons is on trial in this case in any way, and unless counsel has something bearing on the issues I don't think we should spend the time on it. It is wholly immaterial.

The Court:—In view of the objection urged by counsel for defendant the Court will hear from counsel for plaintiff as to the materiality of the inquiry with reference to Dr. Simmons.

Mr. Reynolds:—If we may do so outside of the hearing of the jury. I don't know what it is.

The Court:—Come right up here.
(Out of hearing of the jury.)

Judge Sweeney:—They have attacked Dr. Brunson on the question of advertising, and I want to show Dr. Simmons was an advertiser, and he was the head of this institution, A. M. A., and Dr. Fishbein was working under him.

Mr. Reynolds:—In the first place, counsel, that is not a fact, there is no advertising of Dr. Simmons at any time after he became—

The Court:—I will sustain the exception and will give you a bill, in the interest of time.

Q.—Whose lung is this in this exhibit, Doctor? A.—This is a lung from a human being that died.

Q.—Who is he—who was he? A.—The name of the individual? I can get that for you if you would like to have it. I don't carry it along with me. It is a patient. They are both patients that died, one of them at Fitzsimons General Hospital and one at the University of Colorado School of Medicine.

Q.—Did you attend them at their death? A.—No, sir, I did not.

Q.—Did you administer to them while they were sick? A.—No, sir.

Q.—Neither one? A.—No, sir.

Q.—You got that from the staff of the hospital? A.—I obtained that from those hospitals with which I am personally affiliated.

Q.—And took their statement with reference to the disease from which they died, and the history of the case? A.—Yes, sir.

Q.—You know nothing of that of your own knowledge? A.—Well, no, I wouldn't say I was personally present when they were obtained.

Q.—That is all.

ON RE-DIRECT EXAMINATION

Questions by Mr. Reynolds:

Q.—Doctor, Judge Sweeney just said here you know nothing of the condition of these two people of your own knowledge. As a pathologist have you any knowledge of these conditions? A.—There is not any question about that. I am glad you have asked that question. I studied those materials. I examined them by microscopic examination, and I examined them myself. As a matter of fact I have a section of one of them here with me.

Q.—Doctor, this conference called at the Hilton Hotel with other doctors and attorneys for Dr. Fishbein present on Sunday afternoon—will you tell the Court and jury just what the nature of that conference was? A.—That was a conference in which we were told about the case. We discussed the various phases. Mr. Reynolds spoke of the case, spoke to us on the case, and we were advised what the case was about.

Q.—At any time, in any way, was any statement made as to what you were to testify to? A.—No, sir, I was not told what I was to testify to.

Q.—Were you asked questions about the disease of tuberculosis, in response to which each of you gave answers? A.—Yes, sir.

Q.—Was there any disagreement, Doctor, among all of the doctors present at that time, with regard to the cause, progression, theories and treatment of tuberculosis, as far as the administration of oil was concerned? A.—No, sir.

Mr. Quaid:—We object to that.

The Court:—That probably calls for a conclusion. The Court sustains the exception.

Q.—Dr. Corper, in regard to a complete science, is there any complete science or completely solved science known to mankind? A.—No, there is no such thing as a completed science in any branch.

Q.—Mathematics, physics or chemistry? A.—No, sir. They would cease to be sciences if they were completed.

Q.—Now, Doctor, the question of new remedies and new treatments being advanced in medical science, is there anything new about the theories that we have been discussing and were contained in the treatment contained in the hypothetical question on your direct testimony, that is new and novel in the history of medicine? I mean the inhalation of oils, is that new and novel in medicine? A.—No.

Q.—Do you know whether or not similar treatments have been tried elsewhere? A.—Well, the treatment with these aromatic oils, of course, was attempted many years ago; it is an old treatment as far as that is concerned and it has been discarded.

Q.—It has been definitely established they are of no value? A.—They are worthless.

Q.—That is all.

ON RE-CROSS EXAMINATION

Questions by Judge Sweeney:

Q.—You never gave any such treatment or saw any such treatment given, did you, Doctor? A.—Yes, sir.

Q.—Where and when? A.—Well, unofficially our patients every now and then will get hold of some of these aromatic oils and treat themselves, without the doctor's prescription, and I have seen a number of those cases, that is that spray their throats.

Q.—You have never done it yourself? A.—Prescribe it?

Q.—Yes. A.—No, I would never prescribe it.
Witness excused.

TESTIMONY OF DR. ORVILLE E. EGBERT ON DIRECT EXAMINATION

Questions by Mr. Reynolds:

Orville E. Egbert, El Paso, stated that he has lived in El Paso since 1919. He is a physician, licensed to practice medicine in 1912. He graduated in medicine with the M.D. degree from Baylor University in 1912 and since 1921 has specialized in diseases of the chest. He is a member of the county and state medical associations and the American Medical Association; a fellow of the American College of Physicians certified by the National Board of Internal Medicine. He is president-elect of the Southwestern Medical Association and vice president of the El Paso County Society. He has been a director of St. Joseph's Sanatorium in El Paso since 1927. He did postgraduate work in tuberculosis at the University of Pennsylvania in 1925.

Q.—Doctor, in connection with your study of the treatment of tuberculosis have you had called to your attention any suggested treatments by means of inhalation? A.—Inhalation treatment for tuberculosis has been brought up from time to time for a great many years and it has always been disappointing in its effects. There have been instances when it was tried out, but it has always been disappointing.

Q.—Do you know whether there have been inhalation treatments involving the use of mineral oil or volatile oils? A.—Yes, sir.

Q.—And do you know whether they have proved to be failures or efficacious treatments? A.—The use of oil on mucous membrane is always an irritant, particularly the type of mucous membrane lining the bronchial tree, which is the lung; oils are very irritating. Mineral oil is itself irritating, and volatile oils I should say are even more irritating than mineral oil alone.

Q.—What are volatile oils, Doctor? A.—Those oils that give off volatile or gaseous matter, such as oil of eucalyptus; and there are other such oils.

Q.—Now, Doctor, in connection with the treatment of pulmonary tuberculosis, assume a treatment wherein an atomizer is used, to which is attached an oxygen tank on which the pressure gage is set from 35 to 40 pounds, that the bulb of the atomizer contains an oily solution composed of approximately or substantially 95 per cent mineral oil, the other 5 per cent oil of eucalyptus and menthol, and that by reason of the atomizer mechanism the oil is vaporized, and the tip of the atomizer is placed in the patient's mouth, he inhales ten times, the treatment is administered twice daily; Doctor, have you an opinion based on reasonable medical and scientific certainty as to whether or not such a treatment might or could be efficacious in the treatment of pulmonary tuberculosis, have you an opinion? A.—I have.

Q.—What is your opinion, Doctor? A.—My opinion is that there is no conceivable way in which it could prove efficacious in the treatment of tuberculosis.

Q.—Have you an opinion as to whether it might prove dangerous, might or could prove dangerous? A.—It is my opinion that it would be dangerous.

Q.—Why, doctor? A.—Oil of any sort, oil such as you have described, carrying in solution such agencies as you mentioned in the question, are definitely an irritant, destructive to the mucous membrane of the bronchial tree. In addition to its being an irritant, it would provoke and aggravate cough, and aggravation of cough is very detrimental to the tuberculous patient. The blocking of the small bronchial tubes, even those that go down to microscopic size almost, with even the tiny globules of oil that would be either thrown down there—I do not care what kind of machine, in whatsoever form you got it, if it was a 10 cent atomizer from Walgreen's or this elaborate machine you describe, it makes no difference whatsoever, these oils get down in the bronchial tree and bronchus, block the bronchial tubes and are very liable to produce an area of bronchial pneumonia, one of the most serious diseases of the lung and perhaps the direct cause of death, whether a person is suffering from tuberculosis or any other pulmonary disease.

Q.—This bronchial pneumonia, Doctor, does it have some symptoms which are similar to those of pulmonary tuberculosis? A.—Yes, bronchial pneumonia covers a multitude of sins; or, to put it in another way, it really describes certain conditions and symptoms that may develop in the lung and that may be from various causes. Technically we can have areas of bronchial pneumonia that are tuberculous, tuberculous bronchial pneumonia; it may be due to other germs such as a pneumococcus; the germ of pneumonia or influenza, the germ of "flu." There are many causes of bronchial pneumonia, but it is the thing that we physicians fear perhaps more than any other disease.

Q.—Now, Doctor, in regard to these dangers that you have described in the use of oils, if you should substitute any combination of those oils for the oils I actually described would it make any difference in your answers? A.—In my opinion none whatsoever.

Q.—And if you considered the inhalation of menthol, eucalyptol and turpentine is there any essential difference between those two? A.—Other than in turpentine you have got one more irritant, that is all.

Q.—Dr. Egbert, do you know Dr. Asa Brunson? A.—I have met him on one occasion.

Q.—You know of him? A.—I know of him; I know him at sight.

Q.—Do you know his general reputation as a physician and surgeon in the community of El Paso as it existed prior to January 1938? A.—I do.

Q.—Will you tell the Court and jury what that was? A.—That reputation is not good.

Q.—Doctor, was there any difference, if you know, between his reputation prior to January 1938 in the community in which he resides and his reputation in that same community at the present time? A.—In answering before January 1938 I go back further than that to form my opinion. There is no difference in my opinion in his reputation since or before that date. However, I have not heard of him in the last ten years. I did not know he was even in El Paso until this case came up.

ON CROSS EXAMINATION

Questions by Judge Sweeney:

Q.—Doctor, on what do you base this opinion that you have formed with reference to his reputation? A.—The fact that he is alleged to have treated tuberculosis with a secret remedy, which places it in the category of an unethical procedure, and that, unfortunately, gives him a bad reputation with his fellows and perhaps with the community at large.

Q.—You don't know whether it gives him a bad reputation in the community at large? A.—Yes, sir, it does.

Q.—The bad reputation you speak of is of the medical profession talking about him and knocking him, isn't that a fact? A.—No. We are talking about ethics.

Q.—It is because the medical profession has been talking about him you think he has a bad reputation in this community? A.—I hope, sir, I am talking about the same kind of ethics you are. I will qualify myself if you want me to.

Q.—Go ahead, qualify them anyway you want to, Doctor. A.—I am not talking about a set of ethics that has been set up by some group for their selfish interests. I am talking about ethics as a procedure in human conscience that differentiates between right and wrong. If that happens to apply to the practice of medicine that is all right. Is it right or is it wrong to practice medicine under certain given standards? And that is what I mean by this being an unethical practice of medicine.

Q.—Because he has a secret formula? A.—Yes, sir, that is one thing.

Q.—That is what you base it on? A.—That is one thing.

Q.—Give another thing? A.—Well, let's deal with that—I am willing to let it rest on that.

Q.—Is he dishonest? A.—He is either ignorant or dishonest.

Q.—In what way, how is he dishonest? A.—If he is not ignorant he is dishonest, first because he knows there is no such thing as a secret remedy; he knows that if there was a remedy of value that he could not keep it from the world; and regardless of what his motive might be, it could be 100 per cent selfish and he still would not want to keep it from the world. There is money and honor and everything else for the man who has a true contribution to the suffering people of the world today.

Q.—If he has a secret remedy then, according to your idea, you doctors ought to get that remedy? A.—No, we are not even interested, no, sir.

Q.—You are not even interested? A.—No, sir.

Q.—You have fought him for many years? A.—No, sir.

Q.—The Medical Association? A.—No, sir, absolutely not.

Q.—The Medical Association has talked about him repeatedly, again and again? A.—I never heard his name mentioned in a medical association meeting in my life.

Q.—Now, Doctor, you are a tubercular specialist. Is this your signature (indicating)? A.—May I see it all.

Q.—I asked you if that was your signature? A.—May I see what the whole thing is?

Q.—I will ask you about the whole thing later on. A.—I want to see—

The Court:—He will be permitted to see what it is, and see whether his signature is attached.

A.—Yes, sir.

Q.—Now, Doctor, you know S. E. Jones? A.—I am sorry, my memory is not refreshed on that. That is my signature.

Q.—May I refresh your memory? Do you know a man by the name of S. E. Jones that works for the Nichols Copper Company, in the barrel department? A.—I am sorry, I don't believe I do, Judge.

Q.—That had an affliction of the chest, and you, acting as physician for the Nichols Copper Company, examined him for tuberculosis?

Mr. Reynolds:—Just a moment. There is an objection here. Dr. Egbert is not on trial in this case, and I do not see the materiality.

The Court:—You may come before the Court (out of hearing of the jury).

Judge Sweeney:—He is speaking about attacks and about his knowledge, and likewise as to time lost, and he has a man that he examined and was paid for examining by the Copper Company, and he certified that man as not having lung trouble and made a recommendation and application to the city health department for that man to be permitted to run a lunch counter, and Dr. Tappan, who was then city health officer, had Turner's Laboratory make an x-ray, and he stated that this man has chronic type of fibroid tuberculosis, and that he would not permit him to have a certificate.

The Court:—I don't see the materiality of that.

Mr. Reynolds:—Besides you have not sworn in any witnesses to prove that.

The Court:—No. The Court sustains the exception.

Mr. Quaid:—We would like to have a bill on that.

The Court:—Yes, sir, I will give you a very full bill.

Q.—Doctor, have you met Dr. Watson, Dr. Hruby and Dr. Moorman, and these other doctors that have been here during the past week? A.—Yes, sir.

Q.—Did you attend a conference with those doctors that was had in Mr. Reynolds' room Sunday afternoon, last Sunday afternoon? A.—No, sir.

Q.—Did you attend a conference since? A.—No, sir.

Q.—Have you discussed this case with any of those doctors, what your testimony would be in this case? A.—Discussed Dr. Brunson and his treatment.

Q.—Did you discuss the testimony that they were to give? A.—No, sir.

Q.—Did you discuss anything that you were going to say in reference to the evidence in this case? A.—No, sir.

Q.—Did you discuss inhalation method with those doctors? A.—Yes, sir.

Q.—With whom did you discuss it, Doctor? A.—I imagine I discussed it with all the men you mentioned, Judge.

Q.—At what time, when did you discuss it? A.—Some time during the week, I wouldn't attempt to say what hour or day.

Q.—Can you recall whom you discussed it with during the week, Doctor? A.—I believe I have discussed it with all of the doctors you mentioned, Dr. Hruby and Dr. Moorman.

Q.—Any others, Doctor? A.—I think not.

Witness excused.

Questions by Mr. Harrell:

Friday, June 2

TESTIMONY OF DR. MORRIS FISHBEIN ON DIRECT EXAMINATION

Morris Fishbein, Chicago, stated that he is a regularly licensed physician and surgeon in Illinois. He attended the University of Chicago, graduating in 1910, and Rush Medical College, graduating in 1912, receiving a degree of Bachelor of Science from the University of Chicago and the degree of M.D. from Rush Medical College.

Q.—What has been your work since graduating from the University-Rush Medical College? A.—A large part of the work during the first years was devoted particularly to pathology, since I received the Fellowship of Pathology at the time of graduation. In connection with that work, I participated in about 800 to 900 postmortem examinations which were made in the Cook County Morgue and in various other institutions in and around the city of Chicago. I also did some work in the Central Free Medical Dispensary of Rush Medical College. I was resident physician in the Durand Hospital of the McCormick Institute for infectious diseases. I also carried on research in connection with my work in pathology and in connection with

ectious diseases. I published six scientific contributions during the years 1912 and 1913. I became Assistant Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, and since that time I have kept abreast of medical science by visiting institutions of medicine, hospitals, research institutions, clinics and laboratories throughout the world.

Q.—Doctor, have you contributed articles to medical journals and periodicals? A.—I have contributed a great number of articles to medical journals and periodicals.

Q.—Have you written any articles on the subject of tuberculosis? A.—I have written much in the field of public education regarding tuberculosis, and I have also lectured on the subject of tuberculosis on many occasions.

Q.—You say you have attended clinics. Will you name some of those clinics and what subjects were studied at those clinics, in a general way? A.—Because of the nature of my work, I have endeavored to see the newest advances that are made in every field of medicine year after year, and this I have done particularly since 1924. I have, for instance, within the past 15 years spent several days at Saranac Lake, seeing the very best work done there in the field of tuberculosis. I have also, within the past years, spent time at Colorado Springs and at Denver, visiting various institutions for tuberculosis. I have also been acquainted with and seen work in connection with the Municipal Dispensary and Municipal Sanitarium in the city of Chicago. As far as concerns general medicine, I have visited at least once each year the various large hospitals in the city of New York; within recent months I have seen the latest work on sulfanilamide and sulfapyridine and chemical derivatives of various types. I visited the Mellon Institute in Pittsburgh and have seen research on chemical derivatives of various types. I have also seen institutions for tuberculosis in Switzerland, Sweden and Holland, and have seen such sanatoriums in England.

Q.—Do you contribute articles to newspapers; if so, tell us the nature of the articles? A.—I write a daily column of advice to the public regarding health, which now appears in approximately 250 newspapers each day.

Q.—Do you contribute articles to magazines other than THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and Hygeia? A.—Yes.

Q.—Will you name those magazines and tell us what connection you have with them? A.—For the past five years I have written original articles on the subject of health and on the subject of general science for the *Saturday Evening Post*, *Good Housekeeping* and for the *Reader's Digest*. I am a consulting editor of the *Scientific American*, consulting editor of *Look* magazine, I am consulted occasionally by *Time* and *Life* and *Fortune*; in fact, I have written for most of the magazines of largest circulation in the United States.

Q.—Are you a consulting editor of the *Reader's Digest*? A.—I am consulted frequently by the *Reader's Digest* but I do not have the official title of consulting editor.

Q.—Now, Doctor, what is your official position with the American Medical Association? A.—I am editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, editor of *Hygeia* magazine, editor of the *Quarterly Cumulative Index Medicus*; I am also managing editor of special magazines in the field of medicine, for example the *Archives of Ophthalmology*, the *Archives of Otolaryngology*, the *Archives of Internal Medicine*, the *Archives of Neurology and Psychiatry*, the *American Journal of Diseases of Children* and the *Archives of Pathology*.

Q.—Doctor, what is the American Medical Association? A.—The American Medical Association is an organization, a voluntary organization, of physicians of the United States. On July 1, 1939, it had in its membership 113,113 out of approximately 170,000 physicians who are licensed to practice in the United States. Of these, approximately 15,000 are over 65 years of age and approximately 145,000 are actually in practice. The American Medical Association now includes a voluntary organization of 113,000 plus physicians out of approximately 170,000 in the practice of medicine.

Q.—Doctor, will you name some of the bureaus or councils of the American Medical Association that are concerned with the issues in this case? A.—The American Medical Association has many bureaus and councils, which have their headquarters in the headquarters office in Chicago. In the headquarters office there are employed approximately 600 people, of whom approximately forty are physicians or chemists. In these bureaus those particularly concerned with this case would include, first of all, the Council on Pharmacy and Chemistry of the American Medical Association, of which I am a member. You wish me to describe them as I go along?

Q.—Will you describe the functions of the Council on Pharmacy and Chemistry? A.—The Council on Pharmacy and Chemistry is a body established by the American Medical Association to investigate all discoveries in the field of the use of drugs or chemicals or biologic preparations, such as vaccines, serums or vitamins, in the treatment of disease. The Council on Pharmacy and Chemistry includes seventeen members, fifteen being absent from the headquarters office and all holding chairs as professors in the leading universities of the United States. They cover practically every field of medicine, pharmacy, chemistry and to some extent also biology. The Council on Pharmacy and Chemistry is supported wholly by the American Medical Association. It does not receive financial contributions from any other source. Any one who wishes to establish a new discovery in the field of medicine may submit that discovery voluntarily to the Council on Pharmacy and Chemistry. In submitting the discovery he must state its composition, he must also state the claims that are to be made for the product and submit with that the evidence on which the claims are based. When this is received, the composition of the product, as submitted by the discoverer, manufacturer or promoter, is verified in the laboratories of the American Medical Association, in which five chemists are employed, most of them full time. In addition to that, the claims made for the product, together with the evidence, are submitted not only to the members of the Council on Pharmacy and Chemistry but, if persons are known to have special knowledge, also to such persons; these persons then examine the evidence and determine whether or not the claims made for the product are justifiable by the nature of its composition and the evidence submitted in its behalf. If the product is then found to be acceptable, it is included in a list of acceptable products called New and Non-official Remedies.

Q.—Doctor, will you name the other bureaus or councils that would be concerned with the issues in this case? A.—The next would be the Bureau of Investigation.

Q.—What is the Bureau of Investigation? A.—The Bureau of Investigation was established in 1905, primarily to protect the public but also to protect the medical profession to some extent against various nostrums, panaceas and unestablished remedies offered for the healing of diseases. In the Bureau we now have a cross index system in which there are 300,000 cards cross indexing all of the various remedies, nostrums and peculiar treatments that have been offered to the American people since the time when the Bureau was established in 1905. The investigations made through this Bureau are regularly published in THE JOURNAL and *Hygeia* and various other places; moreover, this Bureau answers approximately 15,000 questions each year that are sent to the Bureau by the public. No charge whatever is made for this service to the people, not even a two cent stamp.

Q.—Now, Doctor, tell us about the chemical laboratory of the American Medical Association. A.—The chemical laboratory of the American Medical Association was established in connection with the Council on Pharmacy and Chemistry in order that we might be able to verify the composition claimed for various remedies submitted to the Council; moreover, when certain individuals endeavor to promote remedies to the American people and are unwilling to submit the composition of the remedy, it then becomes possible through this laboratory, which is equipped with the very latest and finest equipment that can be bought, for us to make for ourselves an analysis of the product in accordance with modern scientific chemistry and thus to determine for ourselves the composition and whether or not the claims made are warranted by the composition.

Q.—Doctor, does the chemical laboratory—strike that. Do you know approximately how many specimens or medicines the chemical laboratory of the American Medical Association analyzes, we will say, within one year's time? A.—Well, certainly never less than 100. In many instances many hundreds of analyses are carried out in this laboratory. I may say that in accord with the most modern advanced scientific chemistry, and with the development of what is known as microchemistry, it now becomes possible very readily to perform an analysis of a remedy frequently within a matter of a few days; there aren't more than ten such laboratories fully equipped in the United States; one of those we possess.

Q.—Is there a microchemist in the employ of the chemical laboratory of the American Medical Association? A.—Yes, sir.

Q.—Tell us his name, please? A.—Dr. Schoeffel.

Q.—Is that the same Dr. E. W. Schoeffel whose deposition has been read here in this case? A.—Yes, sir.

Q.—Now, Doctor, what is THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION? A.—THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is a periodical devoted to all the interests of medical science. It is published once each week, it has approximately 100,000 circulation weekly, the largest circulation of any medical periodical in the world, in fact, almost a larger circulation than all other weekly medical journals in the world combined. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION regularly publishes original contributions from all physicians who have announced new discoveries in the field of medicine and who voluntarily submit to THE JOURNAL not only a complete description of the discovery but also laboratory evidence on which the discovery was based, the animal experiments, the clinical cases and all of the other evidence that the physician may have assembled in relationship to his discovery. No payment is made whatever for such contributions, the physician who has made a great discovery feeling that the publication are quite sufficient reward for the announcement of such discovery and for the submission of his scientific reports by the Association, including the Council on Pharmacy and Chemistry, the Council on Foods, the Council on Physical Therapy, the Bureau of Investigation, the Council on Medical Education and Hospitals, the Bureau of Health Education and other departments.

Q.—What is Hygeia, the Health Magazine, of which you are also editor? A.—Hygeia was established by the Association some fifteen years ago in order to meet a demand from the educators of the United States for a sound periodical in the field of health education. The magazine has thus been accepted, as indicated by the fact, for example, that the state of Tennessee now places a copy of this periodical in each school of that state, also the fact that this periodical has reached approximately 150,000 circulation, also indicated by the fact that it is quite certainly the most quoted of all magazines in its field.

Q.—Doctor, for what purpose or purposes was the American Medical Association formed? A.—The American Medical Association was established in 1847 to advance the standards of medical education in the United States, to raise the standards of medical practice and to protect the public in relationship to such establishment and raising of standards.

Q.—Doctor, assume that a young man graduates from the Medical Department of the University of Texas or of Baylor University, how would he become a member of the American Medical Association? A.—He must first obtain a license to practice in the state in which he lives; he would then apply for membership to the county medical society which exist in the various communities of the United States; there are now some over 2,000 such county medical societies. When he applied to the county medical society, his name would then be regularly posted before the society so that the members of the society might become aware of the fact that he sought admission. If, after a reasonable period of time, no one had made any objection to the type of work in which the man was engaging or his conduct with reference to standards of medical practice, he might be admitted as a member of the county medical society; coincidentally he would become a member of the state medical society. The state medical society would then forward his name as a regular member of the county and state medical societies to the headquarters of the American Medical Association. As part of the work of the American Medical Association, we maintain a complete file of all the physicians now living and practicing in the United States, listing them so far as concerns the high school from which they graduated, the town in which they were born, date of their birth, listing also their high school education, college education, medical education, internship served, if any, residency served, if any, the various communities in which they have practiced from time to time; moreover, there would also be made available any newspaper clippings or other information which might have accumulated from time to time concerning such individual whose name had come into the public print; in addition, there would be assembled, through the Bureau of Investigation, any other information which might develop relative to this physician, and all cross indexed and assembled on cards and envelopes, so for each physician in the United States there is a card and envelop containing all available data concerning him. I might say this is the only place in the United States where such information is available, and, as a result, the United States government, during the World War, stationed its officers in the headquarters office so they might have such information available for building up the medical service of the army, navy, Public Health Service and civilian population.

Q.—Are those names and that information published in any book, do you publish a directory? A.—A directory is published regularly, listing all the information I have mentioned relative to a physician. I might say in this connection also that should it be found that at any time a member of the Association or one that has applied for membership has a record assembled in such a manner, which it is felt should be called to the attention of the county and state medical society who enrolled in individual, that information is sent to the county or state medical society in relation to the affiliation of the individual with the American Medical Association.

Q.—Doctor, do you, as editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and Hygeia, frequently receive inquiries regarding physicians and regarding medicines? A.—There is never a week that passes in which I do not receive a considerable number of such inquiries.

Q.—Does the Bureau of Investigation also receive inquiries? A.—Approximately 15,000 inquiries a year are sent to the Bureau of Investigation from the public.

Q.—Are those inquiries answered? A.—All inquiries are answered and, as I said, without cost to the person inquiring.

Q.—Those inquiries are received from whom, Doctor? A.—Inquiries which come to me directly are in many instances received directly from the public. I answer personally all inquiries which come to me as a result of my own writings either in the newspapers or in the various magazines I mentioned. All inquiries coming from the public without specific request would be assigned to the Bureau of Health Education, which is a general bureau under the directorship of Dr. W. W. Bauer, who answers general questions in that field of medicine from the public. Those having to do with specific unestablished remedies would be sent to the Bureau of Investigation, those having to do with established remedies or food or cosmetics or physical therapies would go to the Division of Foods, Drugs and Physical Therapy.

Q.—Do you receive inquiries from other than individuals? A.—Inquiries are received from practically every large newspaper agency in the United States, such as the Associated Press, United Press, International News Service and Transradio Press Service. Inquiries are regularly received from all leading organizations and associations not only in the field of medicine but general fields, for instance, frequently questions are asked by organizations of laboring men as to the competence of certain physicians, frequently requests are received from sanatoriums and hospitals, from all sorts of institutions for cure of the sick. I have answered in the past four months inquiries from four governors of various states who have sought information on medical problems, medical devices and medical treatments, sometimes regarding individual physicians or hospitals. There is no group or type of individual that has not, at one time or another, sent questions either directly to me or to some of the bureaus or departments of the Association.

Q.—Doctor, do you recall having received this message from DeWitt Wallace, editor of Reader's Digest, and referring to such a telegram.

Q.—After receiving that telegram, Doctor, tell the Court and jury just what you did regarding it. A.—My first step was to send a memorandum to the Bureau of Investigation of the American Medical Association, asking it to send me all material available in the Bureau of Investigation relative to Dr. Brunson or to his method of treatment; my second step was to send a memorandum to the laboratory of the Association and to the Council on Pharmacy and Chemistry, asking them to send me any information there available relative to an analysis of the product said to be used by Dr. Brunson or of similar products; my third step was to address an inquiry to the library of the American Medical Association and to the Quarterly Cumulative Index Medicus, asking them to send me for my desk all periodical articles of importance published within the last twenty years dealing with the subject of inhalation treatment of tuberculosis. The Quarterly Cumulative Index Medicus is an index which is kept up day by day in the headquarters office of the American Medical Association, listing every original article published in more than 1,400 medical journals which are received from every nation in the world, including, for example, the Italian periodicals, Scandinavian periodicals, Spanish periodicals, all of the publications from South America, Mexico and Cuba and every section of the world, and day by day the original articles in these periodicals are regularly indexed, so that at any time we have available the latest information concerning any product or method of treatment.

Q.—What did you receive from the Bureau of Investigation?

Mr. Quaid:—I want to object to that out of the presence of the jury. (Going to Court's desk.) This case is a suit against Dr. Fishbein, and the complaint is that Dr. Fishbein sent the telegram. Now, our courts have held that a tale bearer has no higher standing than a tale maker. It would be no defense what the American Medical Association or some bureau said.

The Court:—There are many features included in here, the question of malice, actual and exemplary damages—the Court overrules the exception.

A.—I received from the Bureau of Investigation what was apparently the original folder there accumulated relative to Dr. Asa Brunson and also relative to the so-called Brunson-Holderness method of treatment of tuberculosis. In the folder were assembled a considerable number of advertisements published from time to time by Dr. Brunson and by the Brunson-Holderness Clinic, as I believe it was called. In addition, there were in the folder perhaps twenty or thirty letters which had come from time to time from various individual citizens asking an opinion of the American Medical Association as to whether or not they should submit themselves to the Brunson treatment or to the Brunson-Holderness treatment. In addition, there was available some correspondence indicating that in 1921 a Chicago chemical laboratory had made an analysis of a specimen of the so-called Brunson-Holderness remedy, and the outline of that analysis was also available in the folder. In connection with the folder, the Bureau of Investigation also submitted a list of other unapproved methods of inhalation treatment of tuberculosis, including, I believe, the Baird inhalant method and the Glass inhalant method, which were first offered to the public in 1910, including also another method of inhalation treatment of tuberculosis, of approximately the same type, offered to the American people in 1918 and including, in addition to that, several modifications or inhalant methods of tuberculosis in the period from '21 and '22 or '23; apparently the only active inhalant method of treatment of tuberculosis being offered to the public to any extent since '23 or '24 was that being offered by Dr. Brunson.

Q.—Was the Dr. Hruby report in the file? A.—There was also in the file, as I have said, a collection of all newspaper clippings dealing with Dr. Brunson, so that I received not only the copy of the original article in the *Herald and Examiner*, to which the name of Dr. Hruby was attached, but also the article by Griffin, which I believe was published in the *El Paso Times*.

Q.—Now, after you had received this material from the Bureau of Investigation and from the chemical laboratory, what did you do? A.—I then investigated all the articles which had been sent to me in various periodicals from the library of the American Medical Association to determine whether or not any scientific contributions dealing with this or similar methods of treatment had been published from time to time.

Q.—Doctor, had you known Dr. Hruby before this occurrence? A.—I had known Dr. Hruby casually from meeting him once or twice at a meeting devoted to tuberculosis. I was not particularly an intimate or friend of Dr. Hruby. However, I was fully familiar with his scientific reputation.

Q.—What was that reputation? A.—His reputation is, of course, that of a leading expert in the field of tuberculosis, primarily because of the vast experience that he has had.

Q.—Of course you knew DeWitt Wallace at that time? A.—I had, I believe, up to that time never met DeWitt Wallace personally.

Q.—Had you had any dealings with him of any sort? A.—I had frequently had dealings with the *Reader's Digest* almost from the time of its founding and with its increasing circulation reached about 2,800,000 copies, I was requested to write contributions for the *Reader's Digest* and I had, previous to January 1938, written several original contributions and in addition had had several of my writings in other magazines and in *Hygeia* requested and abstracted in the *Reader's Digest*.

Q.—What position did DeWitt Wallace have with the *Reader's Digest*? A.—Mr. DeWitt Wallace is editor of the *Reader's Digest* and, I believe, together with Mrs. Wallace, owns most of the *Reader's Digest*.

Q.—At the time that you sent the telegram to DeWitt Wallace did you know Dr. Asa Brunson? A.—No, I never saw Dr. Asa Brunson until I saw him in court here Monday morning.

Q.—Was there anything unusual, Doctor, about answering this single inquiry of DeWitt Wallace's? A.—I receive many such inquiries every week. I have received two such inquiries while here in El Paso, over long distance telephone and by telegram.

Q.—Had you visited El Paso before this time, Doctor? A.—I believe the last time I visited El Paso was in April of last year, and I had never visited El Paso previously, although I had gone through on occasion, once in a sand storm.

Q.—Now, Doctor, you tell the Court and jury your feelings regarding Dr. Brunson. A.—I would say I have no particular feelings of any kind regarding Dr. Brunson. For more than twenty years I have regularly investigated and examined innumerable methods of treatment, innumerable methods of diagnosis and other information in the field of medicine. I endeavor always to be strictly objective in relationship to such examinations, strictly scientific, even in the case of persons whom I know or whom I have met. Obviously, in regard to a person whom I have never seen or whom I have never known or whom I have never personally investigated up to that time, I would have no personal feeling whatever.

Q.—In arriving at the wording of the telegram, Doctor, how did you choose the diction or language used? Tell the Court and jury about that, please? A.—It was my desire to give to Mr. DeWitt Wallace, taking it for granted that he wished honest, scientific information on which to base his opinion, to give him the most accurate scientific advice I could give him. I therefore quoted to him portions of the article of Dr. Hruby, already referred to, and that material was included in the quote in the telegram. However, as a result of my personal knowledge of tuberculosis and of its method of treatment in various leading institutions throughout the world, and as a result of my examination of the scientific literature regarding inhalation methods of treatment which was available to me, and as a result also of my personal knowledge of pathology, and as a result of several recent articles which had been published dealing particularly with the effect of oily substance in the lungs, I added to the quote the final statement, which was to the effect that similar methods elsewhere have also been failures.

CROSS EXAMINATION

By Mr. Sweeney:

Q.—Doctor, you have been connected with the American Medical Association how long? A.—Since September in 1913, late August, early September.

Q.—When did you graduate? A.—I graduated early in June 1912.

Q.—And you have been constantly since that time connected with the American Medical Association? A.—In one capacity or another, yes, sir.

Q.—Who did you first serve under and in what capacity?

A.—I served for three years, including the last year and a half of my medical school and the next year and a half as assistant to Dr. Ludvig Hektoen, who was a professor of pathology in the University of Chicago and who is now chairman of the National Advisory Committee on Cancer.

Q.—Who else? A.—I also did postmortem examinations with Dr. E. R. LeCount, professor of pathology in Rush Medical School. I also did chemical analyses and prepared evidence in legal cases with Dr. Walter S. Haines, professor of toxicology in Rush Medical College. I was also associated in the hospital with Dr. George H. Weaver and Dr. George H. Dick, the latter the inventor of the scarlet fever antitoxin and the discoverer of the cause of scarlet fever. In my work at the Central Free Dispensary of Rush Medical College I was associated with the entire medical staff of Rush Medical College. In fact, I am at the present time clinical assistant professor of medicine in Rush Medical College and lecturer in the history of medicine in the University of Illinois.

Q.—All these things you testified to were in connection with the American Medical Association? A.—None of them.

Q.—I asked you who you served under in the American Medical Association. A.—I understood you meant what my associates had been. You mean in the American Medical Association?

Q.—Yes. A.—I became assistant to Dr. George H. Simmons.

Q.—At what time? A.—Late in August 1913.

Q.—How long did you remain assistant to Dr. Simmons? A.—Until 1924.

Q.—1924? A.—Yes.

Q.—Then how long did Dr. Simmons stay with the American Medical Association? A.—He retired in 1924, when I became editor of THE JOURNAL.

Q.—And during the time that Dr. Simmons was in the position that you now occupy the American Medical Association was still seeking to carry out the fundamentals of the organization? A.—Oh, that was since 1847.

Q.—I say he was then seeking to do that? A.—Yes.

Q.—What was the occasion of his disassociation with the American Medical Association and why did he retire? A.—He was over 70 years old. He was moving up toward 75. He thought, I think, he had done enough.

Q.—What was his general reputation? A.—Well, by—

Mr. Harrell:—I am objecting to that, the general reputation of Dr. Simmons is not an issue in this case.

The Court:—The Court sustains the exception.

Q.—Did you ever see this picture? (Handing book to witness.) A.—Yes, sir, I have seen that picture.

Q.—Was Doctor—

Mr. Harrell:—Your Honor, we have the same question up that was up this morning with reference to Dr. Simmons.

Judge Sweeney:—I asked him if he had ever seen this picture.

The Court:—What is the purpose?

Mr. Quaid:—One of the questions is whether Dr. Brunson advertises, and there is an implication before the jury that the A. M. A. don't believe in advertising. We want to show the most active man connected with the A. M. A. was an advertiser.

Mr. Harrell:—He is not connected with the A. M. A. He is dead now. Whatever advertisements you have there is long before. That stuff pops up in every case we have.

Judge Sweeney:—It is pretty good stuff.

Mr. Harrell:—That book was printed recently. There are several of those books, but that happens to be the one Dr. Brinkley used at his trial, or attempted to use.

Judge Sweeney:—That is not the Brinkley case. This is the Brunson case.

Mr. Harrell:—I say that book was.

Judge Sweeney:—I was going to ask him whether he himself was working for Dr. Simmons, under Dr. Simmons' direction, and if Dr. Simmons' picture there is the method of publicity he had at that time, unethical.

Mr. Harrell:—If you name the date I wouldn't have any objection, that he was working under Dr. Simmons on such and such a date, the date of that picture. It is just a back door way of trying to get it in, Judge.

The Court:—The Court sustains the exception.

Mr. Quaid:—Note our exception.

The Court:—You may interrogate him with reference to ethics if you want to.

Q.—Now, Doctor, you do not believe in advertising do you? A.—Oh, I believe in advertising.

Q.—You, as a doctor? A.—You mean what kind of advertising?

Q.—With reference to your ability and what you can do? A.—I?

Q.—Yes. A.—I have never advertised as to what I could do, my ability, no.

Q.—Are you the most advertised man in the United States in the medical profession? A.—I do not think that is a fair question to ask me. I wouldn't know that.

Q.—You read the papers, you read the magazines? A.—I see my name here and there, yes.

Q.—And you are constantly seeking publicity are you not? A.—Absolutely not, I am constantly avoiding publicity, but I find it very difficult.

Q.—A few weeks ago in St. Louis you had an interview did you not with Richard L. Stokes, a staff correspondent of the Post-Dispatch? A.—No, sir.

Q.—He did not interview you? A.—Not in St. Louis.

Q.—Where did he interview you? A.—He came to see me in my office, I believe in February 1939.

Q.—In 1939? A.—February.

Q.—February. About Baltimore, May 13, 1939? A.—I was in Baltimore May 13, 1939, to speak for the Johns Hopkins University School of Medicine and for the University of Maryland School of Medicine and for the Maryland State Dental Association, and in connection with those public addresses I observed reporters here and there.

Q.—Doctor, you stated at that time that your wife owned all your property, you had no property, did you not?

Mr. Harrell:—I object to that, Your Honor, it is certainly not an issue in this case.

The Court:—The Court sustains the exception.

Q.—Doctor, since you have been in El Paso you have made several speeches have you not? A.—Do you want a list of them?

Q.—I asked if you made several speeches? A.—Many.

Q.—You have made one almost every day? A.—I spoke Tuesday noon for the El Paso Tuberculosis Society, Wednes-

day morning at 6:50 over the telephone to an audience of 250 in Pittsburgh; Wednesday noon to the Twenty-Thirty Club and the Rotary Club; Wednesday night to the El Paso Medical Society and I spoke this noon for the Lions Club, all on their invitation.

Q.—And your speeches were published in the papers? A.—No, sir.

Q.—Some of them? A.—No, sir.

Q.—Some of your remarks? A.—Yes, sir.

Q.—During the course of this trial with reference to medicine— A.—I was exceedingly careful not to discuss this trial and not make any reference to it whatever.

Q.—You did not directly discuss this trial? A.—Under no circumstances.

Q.—Now, Doctor, you have been here since Sunday? A.—I arrived on the airplane Sunday morning about 11:30.

Q.—Did you attend that school of physicians in the Hilton Hotel? A.—I am glad you used the word school; if you had used conference I would say I learned a great deal; it was a school to me, yes, sir.

Q.—Answer the question. A.—I answered it.

Q.—Did you attend the school at the Hilton Hotel? A.—I know of no school at the Hilton Hotel.

Q.—Did you attend the meeting of the doctors at the Hilton Hotel? A.—I listened, remained in the room about thirty minutes, listening to the experts.

Q.—How many of those experts did you talk with on matters pertaining to this case? A.—I do not believe I suggested or said to any expert anything in relation to what he would testify about.

Q.—Doctor, you are the head of one of the most powerful organizations in the United States, are you not? A.—Absolutely not.

Q.—It is not? A.—I am not, no, sir, I am an employee.

Q.—Who is the head of it? A.—The American Medical Association is a corporation not for profit. All of its policies are made by a House of Delegates, which is a representative body like the House of Representatives of the United States government, the county medical society sending a delegate to the state medical society, and the state medical society sending delegates to the American Medical Association, so that all of the policies of the organization are conducted by approximately 170 delegates, sent to the House of Delegates meeting by the physicians throughout the states, who vote according to the number of membership in various places. This House of Delegates then is responsible for electing the elective officers of the Association, including the President, the President-Elect, the Secretary, the Treasurer, the heads of various councils and, in addition to that, a Board of nine trustees who are physicians in practice, selected from various portions of the United States so as to represent the entire country. This Board of Trustees, consisting of nine physicians, I would characterize as the head of the American Medical Association, since they are responsible for the conduct of the affairs of the headquarters office, of the finances of the Association and of the employment of the employees of the Association and I am such an employee.

Q.—And who is in actual charge of them, who operates it that is, the American Medical Association from Chicago? A.—Well, I don't think any one operates the American Medical Association from Chicago. Now, if you are interested in the management of the headquarters office, and who is really in charge of the Association, I presume that is the field?

Q.—Who is really in charge of the Association? A.—The Board of Trustees is in charge of the Association.

Q.—Is the Board located in Chicago? A.—The Board consists of nine physicians, located in various portions of the United States. They meet at regular intervals in the headquarters office to conduct the affairs of the Association. At least once each month the Executive Committee of the Board meets in the headquarters office for conferences with the officials who are in charge of the various divisions of the work of the Association. The Executive Committee then reports to the full Board, which in that way manages the affairs of the American Medical Association.

Q.—Then who is the direct and individual manager up there? A.—We have a secretary and general manager who is responsible for the conduct of the headquarters office; the councils are independent of any management and report directly to the House of Delegates. They do not even report to the Board of Trustees. The business manager is in charge of all business of the Association, and I am personally in charge of THE JOUR-

NAL, of *Hygeia*, of the *Quarterly Cumulative Index Medicus*, of the nine special periodicals and of the work of the library and associated with the health educational functions.

Q.—And the A. M. A. was incorporated in the state of Illinois as a nonprofit organization? A.—Corporation not for profit.

Q.—Now, it possesses approximately \$2,000,000 worth of property, more or less, does it not, in assets? A.—Yes, more or less.

Q.—Is it \$2,000,000? A.—Well, approximately. I should think between, around \$2,200,000 and \$2,300,000, that is in its reserve. In addition to that it has assets in the form of building, property, machinery and employees, who are considered among the assets.

Q.—What are the value of the assets? A.—It is hard to evaluate employees. The tangible assets are perhaps another \$1,000,000 or \$1,500,000.

Q.—What would be the full worth of the A. M. A.?

Mr. Brown:—It seems to me this has gone far enough. We object to it.

The Court:—Yes. The Court can't see the materiality. This proceeding is brought against one individual here.

Judge Sweeney:—It is for the purpose of showing they are a nonprofit organization, and to ascertain where the revenue comes from, and how.

The Court:—We have a suit here against one individual. You haven't a suit against the American Medical Association.

Judge Sweeney:—I know it is not. It is against one individual.

The Court:—The Court sustains the exception.

Q.—Doctor, who is paying for the expenses of this trial? A.—Your expenses or mine?

Q.—You are not paying our expenses. No, yours? A.—My expenses are being paid by my employer, the American Medical Association.

Q.—And the American Medical Association is back of this suit and assisting you in defending this suit, are they not? A.—Back of it? Just how do you mean?

Q.—You know what I mean by defending this suit. They are supporting you in the prosecution of this suit? A.—I would say that the American Medical Association would naturally sustain the expenses of the litigation.

Q.—And all of the experts that you have brought here from the various portions of the country have been sent by the American Medical Association, and at the expense of the American Medical Association, have they not? A.—I haven't the slightest idea, really, who is going to pay their expenses, or whether they will receive any remuneration. I am quite sure none of them has had anything to say about remuneration. As far as they know, or as far as I know, none of them is getting anything.

Q.—Doctor, you stated you had before you when you answered the telegram the full file with reference to Dr. Brunson? A.—Yes, sir.

Q.—How far back did that file go? A.—All the material in the file, or just that about Dr. Brunson?

Q.—About Dr. Brunson? A.—Dr. Brunson's material, I think, went back around 1921 or just before.

Q.—Did you have any letters there from Dr. Brunson to Olin West, Secretary, with reference to an investigation that he wanted to have? A.—I believe there was such a letter, yes.

Q.—Was there any carbon copy of a reply that was made by Olin West? A.—Well, quite frankly, Dr. West as Secretary keeps an entirely separate file, secretarial correspondence, and I would not know whether he had answered it or not.

Q.—That was not a full file? A.—It was a full file they gave me.

Q.—Had Dr. West ever spoken to you about Dr. Brunson asking for an investigation? A.—I don't believe he ever did, at least not prior to the filing of the suit. Since the filing of the suit obviously he must have spoken to me.

Q.—I mean prior to the filing of the suit? A.—No, I don't believe the name of Dr. Brunson ever came up there in the activities of the Association that came directly under my personal inspection, until the time I received the telegram from DeWitt Wallace.

Q.—In response to the telegram from DeWitt Wallace, in which he asked for the facts with reference to the Brunson treatment during the last twelve years, you answered by giving him what purported to be the facts beginning in 1921 of the Brunson-Holderness—

Mr. Reynolds:—Just a moment, your Honor please. I object to that question for the reason it assumes something not in evidence here at all. Judge Sweeney refers in his question, and has before asked for information over twelve years. Such is not the wording of the telegram. The telegram says

what do you think of this treatment, then including a eulogy of Dr. Brunson, stating in the last twelve years he has effected 3,000 cures. The question certainly is improper.

The Court:—The telegram speaks for itself, of course. You can answer the question.

A.—In answering the question may I say that, from my knowledge of tuberculosis and of the inhalation treatment of tuberculosis, the answer to the question, the recommendation made to DeWitt Wallace, would have been approximately the same under almost any circumstances. In other words, all such treatments vary in such slight degree, one from the other, the Glass treatment, the Baird treatment, Holderness-Brunson treatment, Brunson treatment, vary in such slight particulars, one from another, according to the best available knowledge, the telegram would not have been seriously modified if there had been no report from Dr. Hruby, as far as the recommendation that such treatment to 2,800,000 people be not published.

Q.—Did your files show that Brunson and Holderness were in no way connected in 1922, in July 1922? A.—There is reference in the file, I believe, to the best of my memory, to certain data under the name of Holderness-Brunson, Brunson-Holderness, and other data referring just to Brunson. As to the exact demarcation I am not sure whether I am wholly clear; but again I say it would not make very much difference.

Q.—Now, Doctor, you knew that Dr. Hruby's statement referred to the Holderness treatment of 1921? A.—Yes—the Holderness-Brunson, I cannot distinguish between them personally. On the basis of my information I find it very difficult to distinguish between Holderness-Brunson and the Brunson treatment.

Q.—You have heard the testimony in this case? A.—Yes, sir.

Q.—As the Holderness and Brunson—A.—Yes, sir.

Q.—the treatment was the Holderness treatment, did you not? A.—The treatment, as I can conceive of it, is essentially oily inhalation treatment. Beyond that the classification is not significant.

Q.—I am asking of the fact that it is the Holderness treatment? A.—Always referred to in the material which I saw as the Holderness-Brunson or Brunson-Holderness.

Q.—Then as a matter of fact your telegram in response to DeWitt Wallace was with reference to the 1921 treatment? A.—That portion of the telegram quoted from Dr. Hruby's article was obviously related to the publication by Hruby in 1921. That portion which followed was wholly without relationship to that, but with full relationship to modern scientific knowledge of oily inhalant treatment of tuberculosis.

Q.—That was the unquoted language you mean? A.—Yes.

Q.—Then when you made that statement in February of last year to Mr. Wallace you knew that you were not answering DeWitt Wallace's letter with reference to Dr. Brunson? A.—I answered the letter quite definitely.

Q.—And you did not distinguish between the time that it was the Holderness treatment in 1921 and the Brunson treatment subsequently? A.—May I say again that to me that does not make a particle of difference. I knew that the Brunson treatment, so called, was an oil inhalation treatment, I knew the Holderness treatment was an oil inhalation treatment. As far as the patient with tuberculosis is concerned, and as far as our knowledge of the lack of value and possible danger of oil inhalation treatment is concerned, the telegram was fully sound and would apply to either.

Q.—Do you know Ben Altheimer of Chicago? A.—I know him only as a man who wrote me a letter unsolicited.

Q.—Have you got the original letter? A.—Not with me.

Q.—Is that a copy of the original (showing paper to witness)? A.—I would say that was probably an exact copy; I wouldn't swear to it, but it is probably an exact copy.

Judge Sweeney:—We tender that in evidence.

Mr. Harrell:—I am objecting to it, your Honor. It is a self-serving document, the statements in here are not true. It says Mrs. Bradford wrote an article concerning the treatment. Very obviously Mrs. Bradford never wrote such an article. It is hearsay.

The Court:—What letter are you referring to there.

Mr. Quaid:—The letter that Mr. Altheimer wrote to Dr. Fishbein. The answer is in evidence. This is asked to be introduced on the theory of retraction and so on, and failure to retract would be evidentiary of malice.

Mr. Harrell:—I don't agree with you there, counsel, that failure to retract is evidence of malice. A person does not have to retract if he does not want to.

Mr. Quaid:—No, but it is evidentiary.

Mr. Harrell:—Diminishes damages, but I don't think you could increase for failure to retract.

Mr. Quaid:—We pleaded it.

BRUNSON VS. FISHBEIN

ON RE-DIRECT EXAMINATION

Questions by Mr. Harrell:

Mr. Harrell:—It is purely hearsay, matters contained in a letter from a Chicago lawyer, who is obviously plaintiff's agent, and the defendant has no opportunity for cross examination. It is a self-serving document.

The Court:—This letter is admitted in the pleadings, or has been offered in evidence, this letter by Dr. Morris Fishbein to this lawyer?

Mr. Quaid:—Yes, sir.

The Court:—This is not the one. The Court sustains the exception.

Mr. Quaid:—We want to make the offer, restricted offer of that portion that is in the nature of a request for retraction.

Mr. Harrell:—Objection.

The Court:—Let the bill show that.

Mr. Quaid:—Two offers now.

The Court:—You are offering it in its entirety?

Mr. Quaid:—First offered in its entirety, and you overruled that, and now offer the portion relating to retraction.

The Court:—The Court sustains the exception in both instances.

Q.—Now, Doctor, you wrote Mr. Altheimer a letter? A.—I answered the letter.

Q.—Which is in evidence here? A.—I believe so.

Q.—And that was acknowledged, that was your answer? A.—I think so, yes, sir.

Q.—Do you publish this magazine or book (handing same to witness)? A.—It says on the front of the book prepared and issued by the Bureau of Investigation of the American Medical Association.

Q.—Do you print that? A.—I print it? The American Medical Association?

Q.—Yes? A.—Yes, sir.

Q.—The American Medical Association? A.—Yes, sir.

Q.—Now, that is under your direction, is it not? A.—This pamphlet is under my direction?

Q.—Yes, the printing of that pamphlet? A.—Not specifically, but I would say to some extent.

Q.—And the contents of this are governed, more or less, by you, are they not? A.—More or less has a wide range. I would say more or less, yes.

Q.—And this pamphlet is still being published? A.—Yes, sir.

Q.—And is still running this article here? A.—I can't see it from here.

Q.—You looked at it just now, I showed it to you? A.—Which do you mean? You mean the one labeled Brunson-Holderness Gas Treatment?

Q.—You are still running that? A.—To the best of my knowledge is still running, yes, sir.

Judge Sweeney:—We offer this in evidence, Mr. Harrell.

Mr. Harrell:—I am objecting to that, your Honor. That is very counter to their contention here. Certainly that could not hurt Dr. Brunson if he is not using the treatment. He has abandoned it he said.

Judge Sweeney:—That has been published and carrying this article. We are introducing that for the purpose of showing malice.

Mr. Harrell:—There is no evidence as to when this issue there is published. He said it was being published.

Judge Sweeney:—That was bought about six months ago.

The Court:—If you can identify the time of its publication you may do that, if you can establish the time of its publication. Let the Court read the article. If you can identify what time the publication was all right.

Mr. Harrell:—I think he has testified, your Honor, that it is still being published. I will waive my exception as to the time.

The Court:—The Court will overrule the exception and allow it to be introduced.

Judge Sweeney:—Mark it for identification.

Q.—Doctor, what is a nostrum? A.—Nostrum is a remedy without value for the condition for which it is offered and sold for that purpose.

Judge Sweeney:—With permission of the Court I will read this to the jury. The article referred to, being marked "P-1," is as follows,

"Brunson-Holderness Gas Treatment.—Asa Brunson and James S. Holderness exploited from El Paso, Texas, what the newspapers described as the 'gas treatment' for tuberculosis. It was one of the inhalant nostrums and seems to have had a base of liquid petrolatum, in which there were small quantities of oils of turpentine, eucalyptus and menthol, with camphor."

Q.—Doctor, you would not, in your letter to Altheimer, you would not take the opportunity of stating that you were wrong in this matter? You did not take the opportunity of stating that you were wrong? A.—Why should I take such an opportunity?

P-1

Q.—Doctor, I show you plaintiff's Exhibit 1, and will you tell the Court and jury just what that is? A.—This is a pamphlet entitled "Consumption Cures Cough Remedies, etc." In the period of twenty-five years to which I have referred, during which time we have investigated scores and scores of consumption cures, cough remedies and so forth, we have published from time to time articles concerning those which we have investigated. Now, then, this book is a record of such treatments which have been brought up, some of them since 1905, the vast majority of them now out of business. For instance the Glass menthol, which consisted of petrolatum, oil of eucalyptus and inhalant treatment, which consisted of petrolatum and terpene derivatives, was developed around 1910 and after a while it was discarded. Dr. Glass's license was removed by the state of California, and he discontinued his treatment and moved away. The Sartolin treatment consisted of smoking eucalyptus leaves and charcoal. Some one thought that would cure tuberculosis, and he announced it and people breathed it, and then it was found to be without value and was discarded. Now, among others, was the Brunson-Holderness gas treatment, and, as I have said, we have available the approximate analysis of that product made in 1921. You will observe that the article on the Brunson-Holderness gas treatment is entirely in the past tense as far as Brunson-Holderness gas treatment is concerned. Exploited—it does not say exploits but exploited. And thus this is a history of failures in the treatment of tuberculosis.

Q.—But that is still being published now? A.—It is a history of failures.

Q.—And it is being published now? A.—Yes, sir.

At this point Mr. Harrell announced "The defense rests, your Honor."

Then Mr. Quaid said "The plaintiff rests."

Thereupon the jury retired from the court room, and Mr. Brown renewed the motion for an instructed verdict.

THE COURT:—The Court will hear from you now on the proposition presented at that time. The Court deemed it expedient not to pass on it at that time. The Court will hear from the plaintiff and the defense.

Thereupon counsel for the defendant presented his argument in support of the motion for an instructed verdict, and counsel for plaintiff replied thereto, and counsel for defendant replied to plaintiff's argument; whereupon the following proceedings were had:

ON RE-CROSS EXAMINATION

Questions by Judge Sweeney:

Q.—But that is still being published now? A.—It is a history of failures.

Q.—And it is being published now? A.—Yes, sir.

At this point Mr. Harrell announced "The defense rests, your Honor."

Then Mr. Quaid said "The plaintiff rests."

Thereupon the jury retired from the court room, and Mr. Brown renewed the motion for an instructed verdict.

THE COURT:—The Court will hear from you now on the proposition presented at that time. The Court deemed it expedient not to pass on it at that time. The Court will hear from the plaintiff and the defense.

Thereupon counsel for the defendant presented his argument in support of the motion for an instructed verdict, and counsel for plaintiff replied thereto, and counsel for defendant replied to plaintiff's argument; whereupon the following proceedings were had:

The Court:—Mr. Marshal, put the jurors back in the box. The Court, gentlemen, is going to give a peremptory instruction to the jurors to find in favor of the defendant, Morris Fishbein, the Court granting the motion for a peremptory instruction.

Judge Sweeney:—Did you state you were going to instruct the jury to return a verdict for the defendant?

The Court:—Yes.

Judge Sweeney:—Would we be permitted to take a nonsuit?

Mr. Reynolds:—We can't agree to that at all.

The Court:—It is not an agreement, it is a question of law in this state. but now they wait until the time the Court announces his decision, and I doubt very seriously their right.

Mr. Quaid:—We would like for the record to show we asked that before you instructed the jury, this being a jury case.

The Court:—The Court will deny the privilege of entering nonsuit at this time.

The jury thereupon returned to the jury box.

The Court:—Gentlemen of the jury, the Court is disposing of this case on questions of law and as a matter of law by the Court. Therefore the Court instructs the jury in this case to return a verdict in favor of the defendant, Morris Fishbein, which, in effect, withdraws it from the jury as far as submission of any issues of fact for determination by the jury in this case is concerned, the Court disposing of the same as a matter of law. The Court therefore instructs the jury to return a verdict substantially as follows: "We, the jury, under instructions of the Court, find in favor of the defendant, Morris Fishbein." It will not be necessary for you to retire to the jury room from the jury box. The gentleman on the end will act as foreman and will sign the verdict. [Draft of verdict was thereupon signed by the juror indicated by the Court.]

The Court:—The Clerk will read the verdict.

The Clerk (reading):—"We, the jury, under instructions of the Court, find in favor of the defendant, Morris Fishbein," Signed B. F. Littleton, Foreman.

The Court:—The verdict will be received, filed, and judgment entered accordingly.

SATURDAY, JULY 22, 1939

THE MARYLAND MEDICAL EXAMINER ACT

On May 3 the governor of Maryland approved an act of the legislature abolishing the office of coroner in the state of Maryland. For the coroner system, which has functioned in Maryland since colonial days, the act substitutes a "Department of Post Mortem Examiners." "The head of said Department shall be a Commission, consisting of the Professor of Pathology of the University of Maryland, the Professor of Pathology of the Johns Hopkins University, the Director of Health of the State of Maryland, the Commissioner of Health of Baltimore City and the Attorney General of Maryland. The said Commission shall serve without compensation." Obviously the composition of the proposed commission should free it of any taint of political partisanship.

The most important duty of the commission is to appoint, for the city of Baltimore, a chief medical examiner at an annual salary of \$6,500 and two assistant medical examiners at an annual salary of \$5,000 each. These examiners "shall be licensed Doctors of Medicine, and shall have had at least two years post-graduate training in pathology." The commission also appoints, under the merit system of the Baltimore city charter, such clerical and other employees as may be necessary and "shall see that the proper equipment is provided for the use of the Chief Medical Examiner and Assistant Medical Examiners, or shall arrange for the use of the Laboratory and other equipment of the State Department of Health, the Health Department of Baltimore City, the State Police Department and the Police Department of Baltimore City."

For each outlying county the commission appoints a deputy examiner. If necessary, more than one deputy may be appointed for a county. In the selection of deputy examiners, organized medicine receives recognition. The appointments are made from a list of at least two licensed physicians submitted by the local county medical society. Deputy examiners are on a

fee basis. Their work is limited to the view and preliminary investigation. If necropsy or further investigation is necessary, this is done by the chief or assistant medical examiner of Baltimore, the local county paying into the city treasury of Baltimore the sum of \$25 for each case.

The various medical examiners "shall have the power to administer oaths and affirmations, and take affidavits and make examinations as to any matter within the jurisdictions of their respective offices, but . . . shall not have the power or be required to summon a Jury of Inquisition." The medical examiner is required to act "when any person shall die in Baltimore City, or in any County of the State, as a result of violence, or by suicide, or by casualty, or suddenly when in apparent good health or when unattended by a physician or in any suspicious or unusual manner." The records of any medical examiner "shall be received as competent evidence in any Court of this State of the matters and facts therein contained." If the medical examiner's investigation reveals any suspicion of violence or unnatural cause of death, he must submit his observations promptly to the state's attorney. The abolition of the coroner's inquest obviates a feature of most existing coroner laws which makes the necropsy a part of the inquest and thus interferes with proper medical investigation of deaths not due to violence. Thus necessary criminal investigation is placed in the hands of the state's attorney and police officials, where it properly belongs.

In the populous urban jurisdictions of Suffolk County (Boston), Mass., New York City and Essex County (Newark), N. J., the medical examiner system has rendered a high type of medicolegal service. The problem of making a similar type of service statewide in its application and available to less densely populated rural districts was not adequately solved by the statewide medical examiner system adopted by Massachusetts in 1877. The Maryland plan solves the problem by making the Baltimore medical examiner's office a central agency whose services are available throughout the state. This plan might not work equally well in states of larger area. A bill introduced in the recent session of the Michigan legislature, which bill unfortunately died in committee, proposed an appointive state medical examiner responsible for the work of appointive county examiners. In rural districts an examiner might serve two adjacent counties.

The Maryland act makes of the Baltimore medical examiner's office, if competently staffed and properly equipped, a statewide agency comparable to the medicolegal institutes of continental Europe. Since the professors of pathology of the two medical schools of Baltimore are permanent members of the commission, correlation of the work of the examiner's office with the medical school curriculum should be possible and should lead to better instruction in forensic medicine than most medical students now receive.

EARTHWORMS AS CARRIERS OF SWINE INFLUENZA

Earthworms may function as intermediary hosts for the swine influenza virus; while the virus is in the bodies of the earthworms it is "latent" or noninfectious. These basic contributions to modern infectious theory are reported by Shope¹ of the Rockefeller Institute. Swine influenza was first recognized as a clinical entity in 1918, at the time of the pandemic of human influenza. At that time swine influenza was assumed to be a veterinary manifestation of the human disease. In swine the disease is characterized by fever, anorexia, extreme prostration, cough and abdominal breathing, the duration of the prostration being from two to six days and the mortality from 1 to 4 per cent. Economic loss from this disease is mainly due to loss of weight (40 pounds, 18 Kg.) during the acute stage. The few fatalities are apparently due to bronchopneumonia.

Veterinarians of twenty years ago demonstrated that influenza can be transmitted to normal swine by intranasal instillation of bronchial mucus or by a similar instillation of extracts or emulsions of infected lungs. A number of micro-organisms were isolated from such infectious materials, the most constant being an influenza-like bacillus. Pure cultures of this "swine influenza bacillus," however, would not reproduce the disease in normal hogs even when given in massive intranasal doses. Bacteriologists² therefore turned their attention to the possibility that the causative agent is a filtrable virus. Berkefeld filtrates of infectious material, however, were found to be noninfectious for normal hogs. The most that was ever produced by such filtrate was a transient loss of appetite without fever, cough or noticeable prostration.

Shope, however, found that simultaneous inoculation with the presumably noninfectious filtrate and the presumably saprophytic bacillus would cause characteristic fulminating symptoms in normal hogs with a mortality rate of about twice that of the natural infection. He further found that both the natural disease and the artificially induced composite infection led to the development of an effective immunity, convalescent blood in both cases being capable of preventing the disease. Hogs injected with the filtrate alone also developed effective humoral antibodies even though they did not demonstrably come down with the disease. The bacterial vaccines alone, however, were apparently nonimmunizing.

Afterward it was shown by English investigators³ and confirmed by Shope⁴ that the filtrate alone is pathogenic on nasal instillation in mice, regularly producing a fatal pneumonia. The pneumonic lungs of the virus-infected mice were usually sterile bacteriologically but were capable of transmitting pneumonia to normal

mice. By means of the delicate mouse test, accurate virus assays may be made of suspected materials.

Several types of contagiousness for swine influenza were deduced from these data. In the first type, both virus and the concomitant bacillary agent may be transferred in respiratory secretions, causing typical herd epidemics. Or the virus alone or virus accompanied by unrelated strains of bacteria can be transferred. Such fractional infection produces no apparent symptoms but leads to an effective immunity. Finally, *Haemophilus influenzae suis* alone can be transferred in the secretions and may even set up a carrier condition in normal hogs, with the development of no symptoms and no demonstrable immunity.

During the last twenty years an annual outbreak of swine influenza has been recorded in most swine-producing states. Bacteriologic surveys of the swine population in these states during the eight to nine month interepizootic periods showed that the bacterial component of the influenza complex is often found in the upper respiratory tract of recovered swine. The virus component, however, was invariably absent from these animals. The yearly outbreak of the disease, therefore, could not be accounted for as a result of a fortuitous recombination of virus and bacteria as a result of carrier conditions. Some outside reinfection with the virus component was therefore indicated. Search for this outside source eventually narrowed down to an examination of swine lungworms. These nematodes are fairly common in the bronchioles of apparently normal swine in most hog-producing states.

The life cycle of this nematode is fairly well known.⁵ The embryonated ova passed in swine feces are swallowed by earthworms, in the bodies of which the ova hatch as a first stage larva. The larvae eventually develop to the third embryonated stage in the earthworm. The larvae remain in the third embryonated stage until the earthworms are ingested by swine, when they are liberated in the gastrointestinal tract, penetrate the intestinal mucosa and eventually reach the respiratory tract by way of the lymphatics and blood stream. Under favorable conditions the hog to hog earthworm cycle may be completed in thirty days. Under less favorable conditions it may require several years.

In order to test the possibility that this lungworm may serve as the virus carrier, feces and bronchial exudates containing embryonated *Strongylus* ova or adult nematodes were obtained from swine during an attack of swine influenza. This nematode material was mixed with loamy top soil and fed to earthworms. From one to three months later worms were removed from the barrels of top soil and fed to swine. Swine thus fed did not develop demonstrable symptoms or virus-neutralizing antibodies. When such feedings were supplemented by repeated intramuscular injections with living cultures of *Haemophilus influenzae suis*, however, characteristic influenza symptoms resulted, followed by

the development of specific virucidal antibodies. The clinical diagnosis of virus infection was confirmed by mouse inoculations.

The surprising observation was made that the virus is not demonstrable by direct inoculation of mice with emulsions of earthworms known to be carriers of virus-infected larvae. If this observation is confirmed by a larger series of tests, it would suggest the possibility of a saprophytic transformation of the virus in the lungworm or even a complex life cycle in the earthworm analogous to that of certain pathogenic protozoa. Other explanations are, of course, possible. If similar saprophytic transformations of poliomyelitis and other virus diseases occur in nature, much of the conventional epidemiology of these infections will have to be rewritten.

Shope summarizes his tentative conclusion as follows: "Lungworm larvae from pigs with swine influenza harbor swine influenza virus throughout their development both in their intermediary host, the earthworm, and their definitive host, the swine. The virus apparently lies latent within the lungworm after the parasite has finally migrated to the swine respiratory tract and is only liberated or activated to cause infection when a provocative stimulus is applied." In his hands multiple intramuscular injections with living *Haemophilus influenzae suis* cultures or a single intraperitoneal injection with calcium chloride solution were equally effective as this potentiating agent.

Whether or not the swine influenza virus is an aberrant type of the human influenza virus is still controversial. Shope,⁶ however, is inclined to deduce from serologic evidence that "the virus of swine influenza is a surviving prototype of the agent primarily responsible for the great human pandemic of 1918." If this is so, hogs and earthworms may conceivably serve as the source of some future human epidemic.

Current Comment

A NEW DIPHTHERIA ANTITOXIN

The preparation of a new highly purified diphtheria antitoxin of allegedly superior therapeutic properties and almost complete freedom from allergic toxicity has been recently announced by Pope and his colleagues¹ of the Wellcome Laboratories, England. The technic by which this purification was accomplished involved a by-product of a study of heat denaturation of serum proteins. An antidiphtheritic serum containing 7,000 antitoxin units per gram of dissolved protein was changed to a serum fraction containing 27,000 antitoxin units per gram of protein. The result was ascribed to the action of a fibrinolytic enzyme in the serum fraction. A method of large scale purification of diphtheria antitoxin based on this fractional enzymic action has been developed; animal tests of this refined antitoxin indicate that it is more rapidly and completely absorbed

from subcutaneous tissues than native antitoxin. It is also retained longer in the bodies of injected animals and possesses two or three times the therapeutic value of the native antitoxin. Although clinical confirmation is lacking, it is apparent that the possibility that such enzyme purifications may be generally applicable to therapeutic antisera demands prompt investigation.

INSULIN AND METRAZOL IN SCHIZOPHRENIA

Both insulin shock and metrazol therapy seem to be proving beneficial in cases of schizophrenia. The original supposition as to the basis for this effect, however, has been generally rejected. In an attempt to find a common denominator for the mechanism of action of metrazol and insulin on schizophrenic patients, Meduna and Rohny¹ determined the lactic acid content of the blood and the sugar and ketone bodies in the blood of a number of patients treated by these methods. Metrazol was administered according to their usual routine and the lactic acid content of the blood estimated before the intravenous administration of metrazol, immediately after the epileptiform seizures and fifteen, thirty and sixty minutes later. The lactic acid level of schizophrenic patients at rest was found to be normal; immediately after the convulsion there is a steep rise in the lactic acid content of the blood; fifteen minutes after the convulsion the lactic acid values are approximately identical with those obtained immediately after the convulsion, and after thirty and sixty minutes, although a considerable decrease in values is evident, they still have not reached normal. The values of blood sugar obtained on an empty stomach in a resting condition are generally low normal. Immediately after the convulsion there is a small rise in blood sugar, which reaches its high point about thirty minutes after the injection. After an hour there is considerable decrease but the values then obtained are still above the initial level. There is an increase in acetone and diacetic acid after the metrazol convulsion, which reach their maximum level about fifteen minutes after the epileptiform seizure. The effects of insulin therapy indicate that during insulin coma there are no important changes in the lactic acid content of the blood, although there is usually a slight increase. The effect of insulin shock on carbohydrate metabolism however is diametrically opposed to that of the metrazol convulsion. Insulin causes a definite decrease in the sugar content of the blood. These investigators believe that the postconvulsive alterations of carbohydrate metabolism resulting from metrazol in the direction of diabetes mellitus may be considered as reactions of the organism and not as direct results of the action of metrazol. After the administration of insulin the organism endeavors to compensate for the toxic effect of the drug by an alteration of carbohydrate metabolism also in the direction of diabetes mellitus. Although this interpretative hypothesis may not receive general acceptance, the work on which it is based constitutes a study of fundamental importance in the elucidation of the mechanism of the shock treatment of schizophrenia.

ORGANIZATION SECTION

CONFERENCE ON MEDICAL PATENTS

By action of the Board of Trustees, pursuant to a suggestion from the House of Delegates, a conference on medical patents was held at the headquarters building of the American Medical Association March 16, 1939. Dr. Roger I. Lee, member of the Board of Trustees, presided. Representatives of universities with medical schools, officials of state medical societies, pharmaceutical companies having products before the Council on Pharmacy and Chemistry, foundations interested in medical patents and others especially interested in this subject were invited.

PURPOSE OF THE CONFERENCE

CHAIRMAN LEE: On behalf of the Trustees of the American Medical Association, it is a great pleasure to welcome you here. We appreciate that this distinguished group is willing to give some of their precious time, a good deal of their thought and energy to help in this complicated problem of medical patents. This conference, as you know, has been called by the Trustees of the American Medical Association under authorization of a vote of the House of Delegates of the Association in 1938. It is not anticipated that this conference will result in specific resolutions or recommendations but rather in a clarification of this difficult problem, and perhaps in some indication as to proper trends for future programs.

I have no intention of abusing the privilege and honor of presiding over this conference by inflicting on you any extended remarks at this time, although I must confess that I reserve the right of participating in the general discussion perhaps later in the day.

The Constitution of the United States provides that "The Congress shall have the power to promote the progress of science and useful arts by securing for limited times to authors and inventors the exclusive rights to their respective writings and discoveries."

By tradition, the medical profession of this country has felt disinclined to avail itself of the use of patents in medicine. The principles of medical ethics of the American Medical Association upholds this tradition. The Judicial Council of the American Medical Association has exclusive jurisdiction over problems of medical ethics. This council has given most thoughtful consideration to suggestions of change or amendments of the principles of medical ethics in regard to medical patents but has felt it has not been desirable to make any of the proposed changes or amendments.

This course has been approved from time to time by the House of Delegates, the policy-forming body of the American Medical Association. Indeed, certain resolutions were introduced into the House of Delegates with the avowed purpose of developing a more positive attitude against medical patents, of course so far as doctors of medicine were concerned. These resolutions have been referred to the Board of Trustees of the American Medical Association. Thus it is that this conference has been called in the hope that discussion along broad lines may eventually be developed into a working and workable program.

In the meantime the problem becomes larger, much more complicated and much more difficult. What seemed at first to be a problem merely as to whether or not a doctor should receive presumably a small reward for his ingenuity in devising a new gadget like, let us say, a stethoscope, or discovering a new process for making a drug, is all changed. Every time science makes a contact with medicine or public health, new problems arise as far as the possibilities of medical patents are concerned. The single illustration of the so-called biologic products may suffice to convey my meaning. One fundamental change in this problem is that the idea of the doctor as inventor or discoverer is quite supplanted nowadays by the idea of the

invented or discovered object, if that is of value in therapeutics or public health.

In other words, if that change is incorporated into the old tradition, it is no longer a tradition of doctors but a tradition of medicine and public health. At once that may involve any scientist or any scientific laboratory. It involves every university. It involves scientific industry and it certainly involves the public. It is curious, however, that with these changes there seems to be less discussion concerning the monetary rewards to the inventor or discoverer and less said about royalties to the inventor or discoverer.

Certain principles have come to the fore, such as the protection of the public, the maintenance of freedom of research, the relationship of the university or research institution to this whole problem, and the relationship of academic research, so called, and industry.

A BRIEF HISTORY OF THE SCARLET FEVER PATENT

GLADYS H. DICK, M.D.
CHICAGO

Fifteen years ago Dr. George Dick and I published from the John McCormick Institute reports of experimental work which resulted in five different preparations for the prevention and treatment of scarlet fever. At that time we hoped it would not be necessary for the United States Public Health Service to license these various preparations until they could be used under close observation for a period long enough definitely to establish the most effective dosage for each, to study the causes of deterioration of the toxin, and to determine which of the various preservatives used in commercial preparations was most suitable for the toxin. But the immediate demand for the materials resulted in licenses being issued by the United States Public Health Service before any manufacturer was ready to market products suitable for use. And there promptly appeared on the market serums which were nothing more than the old, unconcentrated and unrefined antistreptococcus serums sold under the new label of "Scarlet Fever Antitoxin." The labels of these serums carried claims for potency far beyond any justified by actual tests. They were not effective in the treatment of scarlet fever and caused a high incidence of severe serum disease. Preparations purporting to be appropriate dilutions of scarlet fever toxin were sold for making cutaneous tests to determine susceptibility to scarlet fever. For the most part, these cutaneous test solutions contained no demonstrable toxin. Improperly prepared, unstandardized preparations of scarlet fever toxin were sold for active immunization in any dosage the particular manufacturer chose.

In this chaotic situation it was impossible for the medical profession or the public to derive benefit from the discoveries reports of which had been published. An appeal to Dr. McCoy, director of the Hygienic Laboratory of the United States Public Health Service, now known as the National Institute of Health, resulted in a telegram and the following letter:

TREASURY DEPARTMENT
UNITED STATES
PUBLIC HEALTH SERVICE
WASHINGTON, D. C.

November 12, 1924.

Dr. George F. Dick,
% John McCormick Institute for Infectious Diseases,
2637 South Wood Street, Chicago, Illinois.

Dear Doctor Dick:—

I am amplifying somewhat my telegram of this date in reply to yours sent from Columbus, Ohio, yesterday.

Some months ago, when the streptococci acquired new interest in relation to scarlet fever, we stated to licensed manufacturers, in response to inquiries, that in our opinion there was no objection to marketing packages of antistreptococcus serum for which license was held in such way that it would indicate that the scarlet fever type of organism had been utilized in the immunization of the animals. It is possible that we were

in error in this, but, as I said in my telegram, I believe it would be necessary to have a legal decision to settle this point.

I am sending you a copy of the Biologics regulations, and in the back of the pamphlet you will find the law; there is nothing in the law which actually enables the government to prevent the placing of unlicensed preparations on the market; the law however provides adequate penalties for violation and is enforceable through the usual court proceedings, the action, I take it, being brought in the United States court.

The more we have considered the requirements which you feel should be met the more we have been impressed with the difficulties of commercial production; just at present Dr. Dyer and I feel that the best and perhaps the only way to comply completely with your requirements would be for yourselves to take out patents on your preparations, handling the patents in any manner you see fit. This would give you the opportunity to permit the manufacture in any limited number of places in accordance with your own judgment. I take it that there is no difficulty in this from the ethical point of view because, according to our understanding, this is just what was done by the Toronto group of research workers in connection with insulin.

With kindest regards, I am

Very truly yours,

G. W. McCoy,
Director.

Patented July 28, 1925.

UNITED STATES PATENT OFFICE

George F. Dick and Gladys Henry Dick of Evanston, Illinois, Scarlet-Fever Toxin and Antitoxin and Process for Producing the Same. No Drawing. Application filed November 28, 1924. Serial No. 752,792.

There were certain quality requirements urgently needed at that time:

1. Specificity and accurate standardization of all scarlet fever toxin and of all scarlet fever antitoxin preparations.
2. Refinement and concentration of the serums sold as scarlet fever antitoxin, both to obtain an effective therapeutic or prophylactic dose in a reasonable volume and to eliminate unnecessary serum disease.
3. Prohibition of the addition of horse blood or serum to preparations of the immunizing toxin.
4. A requirement that the various preparations should be distributed in dosage shown to be effective so that the doctor could, if he wished, give enough toxin to prevent, or enough antitoxin to cure, scarlet fever.

We had learned from officers of the United States Public Health Service that they were not in a position to enforce all of these requirements.

You will note that the date of Dr. McCoy's letter is Nov. 12, 1924, a year after publication of reports of the experimental work. During this time the situation had steadily been growing worse. One manufacturer had begun to make quite good antitoxin, but others were apparently engaged in raising the potency claims on their labels.

The idea of a patent which Dr. McCoy suggested was distasteful to us and we could see that it would involve arduous work and trouble of a type to which we had not been accustomed. We were doubtful of our ability to carry it through. But following receipt of Dr. McCoy's letter, we sought advice from Dr. Hektoen, from Dr. Puckner, who was then secretary of the Council on Pharmacy and Chemistry, and from Dr. William H. Welch, all of whom agreed that a patent should be obtained. They pointed out that it offered the only means for obtaining the supplementary quality control necessary. We then applied for a patent. The heading of the patent which was issued is reproduced at the bottom of Dr. McCoy's letter. You will note that it gives the application date as Nov. 28, 1924, sixteen days after the letter was written.

The first part of the interval between this date and issuance of the patent on July 28, 1925, was employed in seeking advice as to the best method of administration. We were surprised to find a unanimous agreement against assigning the patent to an institution or to a university and in favor of Dr. McCoy's suggestion that a committee be formed for the sole purpose of administering this patent as the most effective method of insuring that it would not degenerate into a patent for revenue rather than one for the control of quality and improvement of the products.

A committee was formed, consisting of Dr. Hektoen, director of the John McCormick Institute, where the scarlet fever work had been accomplished; Mr. Wallace R. Lane, a Chicago lawyer who had donated his services and had helped finance the expense in connection with obtaining the patent, because after consulting with various doctors, including Dr. Pusey, then president of the American Medical Association, and his own brother on the faculty of Yale Medical School, he had concluded that it was

for the public good; Mr. and Mrs. James A. Patten, well known philanthropists; Mr. Arthur G. Leonard, president of the Union Stocks Yards and Transit Company, who had generously financed the work on scarlet fever antitoxin, furnishing barns, horses and veterinarians; and Dr. George Dick and myself.

The first duty of the Scarlet Fever Committee was to make good materials available. Its second duty was to get the poor materials off the market.

It appeared that in order to accomplish the first purpose it might be necessary to manufacture the products. For this reason the Scarlet Fever Committee was incorporated June 27, 1925, under a charter which would permit it to engage in production and distribution if necessary. From the time the patent was issued in July till the first of October it was ignored by manufacturers, who continued to distribute inadequate preparations. This made the necessity for manufacture by the Scarlet Fever Committee appear probable, and arrangements for this were about to be made when Mr. Weicker of E. R. Squibb and Sons came to Chicago to request an exclusive license. We had been advised against granting an exclusive license for two reasons: (1) it gives the licensed manufacturer an unearned advantage, and (2) the period covered by a patent is necessarily one of education and improvement from which no manufacturer who may eventually produce the materials should be excluded.

For these reasons it had been decided to license all commercial manufacturers of good repute, who were licensed by the United States Public Health Service, on a uniform basis that would ensure a wide and inexpensive distribution. Free licenses were issued to manufacturing health departments. The work of the Scarlet Fever Committee was to be confined to research directed toward improving the products and to the control of specificity, quality, potency, dosage and advertising literature, leaving responsibility for sterility and such other factors as they were in a position to control with the United States Public Health Service.

E. R. Squibb and Sons decided to take a nonexclusive license, thus relieving the Scarlet Fever Committee of the immediate necessity for manufacturing. The following days were strenuous, as Mr. Weicker went over the license contract prepared by our lawyers and every phrase was discussed at length. Modifications were made where he was able to demonstrate from his long experience that they were indicated. Thus the license contract, as it stands, was the result of cooperation between research and commercial manufacture, supervised by expert legal minds. It is probably because of this that no situation has ever arisen which was not provided for in the original contract. It has enough flexibility to permit prompt adoption of improvements and is rigid enough to furnish control of quality.

The mere signing of a contract does not necessarily result in good materials. This requires hard work on the part of both the licensor and the licensee.

Following this first license, other manufacturers appeared at intervals of several months until most of the leading manufacturers were operating under licenses and supplying the market with specific, standardized preparations, distributed in proper dosage.

It was then time to turn to the second duty of the Scarlet Fever Committee, that of removing from the market products of poor quality made by unlicensed¹ manufacturers. There was some urgency in this, as unlicensed manufacturers, because they were free to exaggerate the potency of their products, had an advantage in seeking large contracts such as those with the Army, Navy and the various health departments. This penalized manufacturers who were trying to market good, correctly labeled materials and resulted in a wider use of the poor products against which we were trying to protect the public.

The first step toward ridding the market of inadequate and falsely labeled products was an attempt to persuade the manufacturers concerned that it would be to their own interest as well as that of the public to take out a license and avail themselves of the help and experience the Scarlet Fever Committee could offer.

1. Throughout this report the term "licensed" is used to indicate manufacturers or products licensed under the patent as well as licensed by the United States Public Health Service, and the term "unlicensed" refers to manufacturers or products not licensed under the patent, although licensed by the United States Public Health Service.

In the conferences it soon became apparent that there was a definite reason for their refusal to cooperate. As stated to us, this reason was that, while they approved patents for profit, they did not approve patents for the control of quality. One manufacturer offered to sign a contract requiring twice the usual royalty payments, providing his products would not be subjected to quality control. We were told that the precedent of a United States patent for the control of quality must be destroyed. He explained that, although he understood the Scarlet Fever Committee was fair and reasonable, most scien-

Chart 1.—Typical result with an unlicensed product: Temperature curve in a case of scarlet fever treated with two doses of improperly prepared serum. A, 20 cc. of serum given on first day of rash; B, 20 cc. of serum.

tists who made discoveries of importance would prove temperamental, and if the patent on scarlet fever toxin and antitoxin was allowed to stand, the manufacturers might find themselves greatly hampered by patents for the control of quality administered by unreasonable people.

Thus the infringement suit which the Scarlet Fever Committee instituted against an unlicensed manufacturer was actually a suit to learn whether or not the precedent of a patent for the control of quality would be permitted to stand. In view of this we did not expect any help from our own licensees. It seemed reasonable that they would assist the defendant in any way they could without jeopardizing their own position and that they might help defray the expense of the defense.

Mr. Lane had repeatedly warned us that the granting of a patent in the United States often amounts to conferring the privilege of instituting an infringement suit. Since it had for some time been apparent that a suit could not be avoided, preparation for it was begun before the defendant was selected. Since we preferred to have but one such suit, it seemed advisable to select as defendant a strong company, capable of employing the best legal talent and defending itself so well that other infringers would be convinced that they had little hope of winning if the first defendant lost. Since the proceedings were to take place in New York, and the Lederle Laboratories had been distributing preparations of both the toxin and the antitoxin believed by the Scarlet Fever Committee to be undesirable, they were selected as defendant. Suit was filed against them and it eventually came to trial in the federal court of the Southern District of New York. It lasted six weeks and was one of the longest and hardest fought battles in the history of that court. The decision established the complete validity of the patent on scarlet fever toxin and scarlet fever antitoxin, enjoined the defendant from further manufacture or distribution of these products without a license and compelled payment of damages. This company has since secured and is operating under a license from the Scarlet Fever Committee. Following this decision Eli Lilly and Sons, still refusing to accept a license, voluntarily agreed to refrain from the manufacture or distribution of the scarlet fever toxin and antitoxin and paid damages for past infringements. Other unlicensed manufacturers sought licenses.

Having succeeded in removing from the market the products which gave unsatisfactory results because of poor quality or lack of standardization, the Scarlet Fever Committee was free to devote all its facilities to testing the products of licensed manufacturers and investigations directed toward improving the quality and the efficacy of these products.

Investigations had shown that scarlet fever toxin, like many other biologic materials, is extremely sensitive to changes in reaction toward either the acid or the alkaline side. It was found that, if toxin is passed through porcelain filters after it is diluted, it deteriorates because of absorption of alkali from

the porcelain. Some factories were unable to fill the diluted toxin which we furnished them in bulk without loss of potency. It was learned that this was due to soluble alkali in the burets, in the rubber connections and in the final containers, or in the rubber stoppers employed. Manufacturers who used the best grade of nonsoluble glass were also troubled by deterioration of their toxin, owing to soluble alkali in their rubber stoppers. Investigation showed that the soluble substances in the rubber stoppers may be due to the chemicals used in the compound but that they may also come from green soap employed to lubricate the molds or from caustic soda used for cleaning the molds. The rubber stopper problem was solved by the use of pure gum rubber stoppers poured in chromium plated molds without the use of a lubricant.

The problem of alkali in glass is still vexatious. Even with glass containing a minimum of alkali, heating to mold into ampules or vials causes some decomposition, accompanied by release of an alkaline vapor which, when the molded container is cooled, is deposited in a film on the inner surface of the vial or ampule. This film can be removed by careful washing, but it is often not removed before the container is filled. It is frequently the cause of deterioration in sensitive biologic or chemical preparations.

Slight amounts of alkali in distilled water employed for making dilutions is another common cause of deterioration.

The difficulties with glass, rubber and distilled water are cited as examples of the numerous technical problems the Scarlet Fever Committee has had to solve for the manufacturers. In addition to solving such problems, we have maintained clinical material and assistants for testing every filling of every dilution of all lots of each kind of material produced by all licensed manufacturers. We had hoped that, with experience, the manufacturers would become increasingly independent so that it would be necessary to test only an occasional lot from each factory and that they would be fully self sufficient before expiration of the patent. There appears to be little hope of this, as we still find it necessary to refuse as unsuitable for distribution on the basis of claimed potency from 4 to 15 per cent of the products submitted for test.

It has been claimed that a patent interferes with improvement of the products. That the opposite is true is shown by the steady improvement in the quality and potency of scarlet fever toxin and antitoxin. To illustrate this, I have brought samples of scarlet fever antitoxin made by unlicensed manufacturers and by licensed producers; some made by the same manufacturers before and after license under the patent. Not only are the licensed products smaller in volume and higher in potency, but the temperature charts indicate that there is a corresponding difference in clinical results.

The toxin has been improved through reduction of the protein content by the use of synthetic medium and by chemical purification. The purified toxin is made by a process which results in a white powder containing from 25,000,000 to 40,000,000 skin test doses per gram. This is the most potent biologic product available. Experiments on further purification are in progress.

It has been claimed that a patent interferes with research. So far as we know, complaints on this ground have come from two sources: first, those who wished to distribute a formalized preparation of scarlet fever toxin under the name of "Scarlet Fever Toxoid" and, second, from those who wished to distribute scarlet fever toxin under the name of "Scarlet Fever Phage."

Thus far the existence of a scarlet fever toxoid has not been established, and after thorough investigation the Scarlet Fever Committee refused to license manufacture and sale of a substance not known to exist.

Chart 2.—Typical result with a licensed product: Typical temperature curve in a case of scarlet fever treated with scarlet fever antitoxin on third day of disease, first day of rash. A, one therapeutic dose; temperature normal next day.

The second complaint came from a laboratory which distributed a "phage" for active immunization against scarlet fever. This product was actually an unstandardized preparation of scarlet fever toxin prepared by the customary method. It was not necessary to resort to legal means to stop the distribution of this unstandardized preparation of scarlet fever toxin. It was necessary only to explain the nature of the product, and the manufacturer readily agreed to discontinue its distribution, taking out a license for the manufacture of standardized products.

Thus it will be seen that the complaints as to interference with research have come not from scientists who wished to do actual research but only from persons who desired large scale distribution of materials accompanied by claims for which there was no scientific basis. The advocates of such products have failed to do the fundamental scientific investigation, which should be made, first, to establish the existence of the substance and, second, to determine its efficacy before wide distribution is begun. The Scarlet Fever Committee in administration of the patent has never interfered with research. It has frequently furnished material for scientific experiments and, when indicated, cooperated in the work. It has, on the other hand, refused to license the commercial manufacture or distribution of harmful or ineffective products.

That a patent under which existing, competitive commercial manufacturers are licensed on equal terms affords the best means of obtaining good material is readily shown by comparison of scarlet fever products on the market in this country with those available in countries where we have no patent. Specific, highly potent and accurately standardized scarlet fever toxin and antitoxin are produced only in those countries where the products are protected by a patent. In countries where state serum institutes have a monopoly and competition is lacking, they are decidedly inferior.

We have been asked whether the licensed manufacturers have cooperated with us. We have no reason to believe that manufacturers opposed to patents for the control of quality have given up their traditional hostility toward such patents. On the other hand, commercial manufacturers have been responsible for some of the most important improvements. Their attitude has always been friendly and, in view of the facts that they were working under new conditions, were attempting to produce extremely sensitive substances which could be standardized only on human beings and were fearful of patents for the control of quality, they have given remarkably good cooperation.

COMMENT

CHAIRMAN LEE: While there may have been controversies over the Dick patent, I am sure the Dicks themselves, Dr. George F. and Dr. Gladys H. Dick, are much in financial debt on account of that particular patent. I think that statement can go absolutely unqualified; in no way has the so-called Dick patent redounded in any financial benefit to the Dicks, Dr. George F. or Dr. Gladys H. Dick, in any way, form or fashion.

THE ADMINISTRATION OF MEDICAL PATENTS FOR THE PUBLIC WELFARE

F. LORNE HUTCHISON

Secretary, Insulin Committee, University of Toronto
TORONTO

I am here today neither as an apostle nor as a disciple but simply as one who has had some experience in connection with the administration of medical patents. As executive secretary of the Insulin Committee of the University of Toronto since 1923 I have had duties in behalf of the holders of certain patents, and as comptroller of the Connaught Laboratories of this university since 1925 I have had duties in behalf of these laboratories as licensees under other patents. Hence my acquaintance with the subject of medical patents has been both from the standpoint of licensors and from the standpoint of licensees. What credos have I reached regarding this subject? I propose to answer this question for you not with a view to proselytizing any of you who are either apostles or disciples having a creed differing from mine; and not with a view to

converting any of you to my creed, but simply in order that you may all know the position which I take and from which I am speaking to you.

I believe that it would be a misfortune were it not possible to obtain patents relating to medicaments; that in respect of patenting of discoveries and inventions in the field of medicine (or food) there should be legislative restrictions of a sort that would be unnecessary or undesirable in other fields; that it would be desirable if most of the patentable discoveries and inventions related to medicine were to be patented only if otherwise they would be kept secret and would not be fully disclosed by exhibition and publication; that it is very definitely in the public interest for certain discoveries and inventions in the field of medicine to be patented; and I believe that whenever it is in the public interest for a medical patent to be obtained it should be considered as wholly proper for the inventor to apply for the patent irrespective of whether or not he is a member of the medical profession, and that it should be considered as wholly proper for him or for any noncommercial organization, such as a university, to receive the patent and hold or administer it for the public welfare.

Present or future holders of medical patents that are being or could be administered for the public welfare fall into three categories. A common impression to the contrary, commercial manufacturers are not simply birds of prey, and it is by no means impossible or unheard of for manufacturers or others having a profit motive to hold and administer a patent unselfishly. None of them can be expected, however, to administer commercially valuable patents wholly or even primarily for the good of the general public. Some of them are bound to abuse and undoubtedly do abuse their proprietary rights. Obviously any such abuse is particularly deplorable when it affects the question of medicine or food; and it is with this in mind that patents relating to medicines and foods are often the subject of restrictive legislation designed to minimize abuses but retain the uses of such patents. An example of such legislation reads as follows:

In the case of inventions relating to substances prepared or produced by chemical processes and intended for food or medicine, the specification shall not include claims for the substance itself, except when prepared or produced by the special methods or processes of manufacture described and claimed or by their obvious chemical equivalents.

In the case of any patent for an invention intended for or capable of being used for the preparation or production of food or medicine, the Commissioner shall, unless he sees good reason to the contrary, grant to any person applying for the same, a license limited to the use of the invention for the purposes of the preparation or production of food or medicine but not otherwise; and, in settling the terms of such license and fixing the amount of royalty or other consideration payable, the Commissioner shall have regard to the desirability of making the food or medicine available to the public at the lowest possible price consistent with giving to the inventor due reward for the research leading to the invention.

What I have just read is taken from the Canadian Patent Act and is perhaps quite imperfect, but I feel that something along the lines of this legislation is worthy of consideration for adoption.

Next let us consider for a moment the case of the man who has no profit motive in connection with an invention of his of value in the field of medicine but who finds that it would be definitely in the public interest for the invention to be patented. Rarely would this man have the resources required for the obtaining of a patent and the capacity and facilities necessary to administer the patent in the public welfare. To achieve these ends it is logical for him to turn to some noncommercial organization, existent or specially created, able and willing to assume responsibility for the desired administration of the patent.

Here we come to the third category of holders of medical patents, namely universities and other noncommercial institutions and organizations which have undertaken administration of the patents. It seems to me that features which are outstanding if administration of a medical patent is genuinely for the public welfare are:

1. It was necessary to apply for the patent in order to ensure one or more or all of certain desiderata, some of which involved protection of the public interest and the remainder of which involved appropriate control of practice of the invention to which the patent relates. These desiderata are:

- (a) That the invention be put into regular practice without being patented by some one other than the actual inventor.

(b) That it be made impracticable for exploitation to result from the discovering and patenting of an improvement of the prime invention.

(c) That the invention would not fail to be practiced simply because its translation to large scale utilization would require so much expenditure that commercial manufacturers could not reasonably be expected to undertake this without the measure of insurance which a patent would give them.

(d) That eminently necessary or desirable control of practice of the invention, not suitably available through already established channels, be provided.

2. If the patent was necessary simply for protection of the public interest, the institution makes, either actually or in effect, a dedication of the patent to the public.

3. If control of practice of the invention is eminently necessary or desirable and is not suitably available through already established channels, the institution arranges for such control.

Control of the practice of an invention covered by a medical patent is clearly a major operation. It may be considered as falling under the headings of licensing, standards, prices, claims and finances. Under these five headings the views which I hold in the matter of administration of medical patents for the public welfare may be summarized as follows:

Licensing.—A comprehensive, appropriate form of license is of prime importance. The making of exclusive licenses, subject to adequate safeguards, has distinct advantages but almost insuperable disadvantages for noncommercial institutions. Sometimes, however, as in the case of the original licenses under insulin patents, force of circumstances leaves absolutely no practicable alternative to the granting of an exclusive license; but it is desirable that the period of exclusive license be limited as much as possible. Usually this can be confined to a year or very little more than a year.

Standards.—In respect of standards, the prime thing is establishment and maintenance of the highest standards of quality, which can usually be done only through regularly subjecting manufacturers' products to laboratory tests carried out as a responsibility of the licensing authority under the patent or patents concerned. In this connection the holder of a medical patent can and should make rulings not only as to what preparations are of quality acceptable for release to the market but also as to what preparations would desirably be withheld from the market irrespective of their quality. Any such ruling would usually be beyond the jurisdiction which it is practicable and desirable for governmental licensing authorities to have. Similarly the holder of a medical patent is in the position of being able to make rulings as to the exact nature and form of preparations that are supplied for clinical trial. Such rulings should certainly be made provided they establish no actual impediment to research and provided they serve the purpose of ensuring as far as possible that the results of clinical trials will be significant.

Prices.—Patentees may lawfully fix prices at which goods manufactured under their patent shall be sold. This being the case, it seems obvious that holders of medical patents have both a right and a duty regarding prices. Desirably these prices should be controlled so that there is no exploitation of patents and so that the manufacturer's returns are sufficient to allow him a profit that is small but sufficient to keep him satisfied to maintain the quality of his product or even to improve this quality through research.

Claims.—The holders of medical patents are in a particularly good position and have a duty to weed out sins both of commission and of omission in connection with advertising and literature issued by licensees and to cooperate with licensees to the end that printed matter relating to licensed products be phrased so as not to be confusing or misleading.

Finances.—If a medical patent is obtained purely for protection of the public interest, the funds required can usually be raised without difficulty, and it seems to me to be desirable that either nothing or merely a nominal fee to cover expenses should be charged for rights under the patent. On the other hand, when there is occasion for the holder of a medical patent to render constant public service in controlling the manufacture and distribution of products, I see no contraindication whatever to the licensor's collection of a small royalty to be used in

defraying his expenses and to leave a balance for devotion to purposes of medical research. I feel, however, that whenever possible it is desirable to avoid paying any portion of the royalty or any other like remuneration to the person or persons who filed the original application for the patent concerned.

Attention to the details which I have summarized under five headings requires a definite organization within the institution, or without the institution, corporate or noncorporate. That organization has, of course, a board of direction, but irrespective of whether this consists of a committee or whether its members are called directors or trustees the board of direction should be made up of men of affairs, on the one hand, and men representing the sciences, fundamental and applied, on the other.

The mere creation of a board, a committee, a foundation or a corporation to hold and administer a patent is nowhere nearly enough. There must be full-time activity in connection with administration and control. There must be a staff, there must be facilities designated for dealing with the manifold items requiring the attention of any one who is administering a medical patent for the public welfare. Usually a testing laboratory is required. It is very fortunate also if the holder of the patent conducts even on a small scale the regular production on at least a semicommercial basis of the product or article which is being licensed.

The organization must be so arranged that services can be given to licensees, because the licensee immobilizes a good deal of money represented by stocks awaiting a release on a report from the testing laboratory, and if there is not cooperation with him in that respect there is lack of economy for him and, in the last analysis, the public pays for this.

If a patent is to be administered for the public welfare, the flag at the top of the pole must always be that of the patient. I don't mean for a moment that the interests of those who serve the patient, particularly the physician, nurses, hospitals, druggists, pharmacists, can be or should be disregarded, but if the patent is to be administered for the public welfare it must be the welfare of the patient that rules.

There are pitfalls for any one who attempts to administer a patent for the public welfare. Some years ago the president of a university in this country was wise enough, when asking the president of the University of Toronto about the control of insulin, to make particular inquiries as to pitfalls. He wrote "I would be grateful if you would give me details of the plan and especially advice regarding the pitfalls into which a relationship of this type may lead the university."

In respect of this request I wrote as follows: "You will readily appreciate that by no means all medical discoveries would warrant treatment such as the University of Toronto gave to the discovery of insulin. Tomorrow, at this or some other university, there might be made a discovery more notable than the discovery of insulin without there being any occasion for the university to handle the matter in the way the discovery of insulin was handled.

"Let us suppose, however, that the circumstances pertaining to a medical discovery are such that a university decides to follow a course similar to the one followed by the University of Toronto in respect of insulin. One of its prime and constant cares should then be to guard against leaving itself open in any way to having policies dictated to it, directly or indirectly, by commercial interests represented by licensees or otherwise.

"Another of many things to be guarded against would be the tendency for its control to be extended abroad, beyond the confines of the territory in which it could be of distinct useful service."

Those two pitfalls in particular were pointed out in response to the request made by the president of the university concerned and, unfortunately, the university would appear to have fallen into both of them very definitely.

Now I want to say that, when I mentioned the pitfall of having policies dictated directly or indirectly by commercial interests represented by licensees or otherwise, I was not taking a slap at commercial manufacturers. My experience with commercial manufacturers, in this country at least, is that they are very decent people, by and large; that they compare very favorably indeed in ethics and morals and ability with people in other walks of life. Of course, among them there have been

crooks, but in what profession, what trade, what walk of life are there no reprehensible characters?

I have here a list of commercial manufacturers in alphabetical order—Abbott, Lederle, Lilly, Merck, Parke-Davis, Sharp & Dohme, Squibb, Stearns. These and many others are names which to all of you are by-words. The men in charge of those companies, although of course they must naturally have a profit motive, are big enough and broad enough to realize that it is in their interest to serve the public interest, and they make it their endeavor to do this. A difficulty, however, is that commercial competition is comparable to war, and what commercial manufacturers sometimes feel they have to do and sometimes do as a result of the stress and strain of commercial competition is indeed most unfortunate.

The other pitfall I mentioned, about extending control abroad, beyond the confines of territory in which distinctly useful service can be rendered, was another that I am afraid the university to which I referred did not succeed in avoiding. But the fact remains that I know of no noncommercial licensor, no university, no corporation or foundation which, in its attempt to administer patents for the public welfare, has not made distinct mistakes. I know of not one. A rather unfortunate thing, in my judgment, is that it seems often that a licensor might profit by the experience and mistakes of his fellows who have been licensors before him, and often that is not done, as in the case to which I referred.

DISCUSSION

MR. JOHN UNGER (Medical Society of Pennsylvania), Pittsburgh: Some methods and procedures must be adopted which will safeguard the health of the public and give them as good a preparation as can possibly be maintained. However, there is one portion of these papers on which I am not entirely clear. As I understand it, patents entail research work on the scarlet fever streptococcus, and the literature associated with such research. I fail to understand why it would be against public welfare to have research workers entirely unhampered in their pursuit in this line of investigation or any similar line. I know they have been hampered and I myself have been a victim of such a situation. There is held at present a patent by a certain layman covering the removal of blood from the body, its ultraviolet irradiation and its reinjection into the body. The entire process is covered by the patent. For the past two years I have been working, in an experimental way, on a similar problem. By virtue of the fact that the patent is a broad and inclusive one, I am not permitted to publish the results of my investigation. I have had several conferences with one of the patent owners, and at one time he promised he would give me a letter releasing me from any possible prosecution in case I should publish anything on the subject, but though I presented a letter of request to him his permission has not yet been forthcoming. I think if patent rights cover a field so broad, research work is certain to be hampered.

DR. GREGORY STRAGNELL (Schering Corporation), Bloomfield, N. J.: I believe, basically, the entire patent situation, while it may require clarification in order to iron out certain injustices that may be operating, certain difficulties for the inventor, certain additional safeguards for the public and sufficient leeway for the manufacturer or laboratories, is not nearly as bad as has been made out by some persons. I am not defending the entire situation as it stands. I do believe that the work on insulin, the way it has been handled by the inventors, the cooperation of the very fine firms that have handled it and the benefits that have eventually been given to the public, the quality of its product, its price and all would be difficult to criticize either here or abroad. Of course, abroad they didn't take sufficient safeguards, but I don't believe the situation has been on the whole lamentable even abroad. As a matter of fact, I think if we only had insulin to cite that no one would have cause to complain. I was a bit amazed, if I may be permitted to comment, by the remarks of Mr. Unger. I believe him to be in error. We who hold many patents in many fields have never at any time refused or disallowed any individual work to be done under those patents. There has always

been complete freedom of using all the methods or any methods we employ for research work, without any restriction whatever. The only restriction we have ever placed is where the product of such work would be commercially offered; but as far as any research work is concerned, as far as I know and other commercial houses that I can speak for, I know of no such condition prevailing as has been stated.

MR. R. A. NORTON (Calco Chemical Company, Inc.), Bound Brook, N. J.: I should like to make a few remarks on one phase of Dr. Dick's able presentation of the work of the Scarlet Fever Committee, and that is the point she made that there was an objection by the manufacturers with whom her committee came in contact to the use of patents to control quality. I am not in position to answer with regard to manufacturers generally. I am personally acquainted only with the policies of the company for whom I do patent work. I hope Dr. Dick has drawn an incorrect conclusion, because I think that attitude, if it is generally true of the manufacturers, would be an unfortunate one. I can speak for my own company and for my own opinion that we believe one of the functions of a patent dealing with medical treatment, or with substances or drugs which are to be used in it, is the possibility which that patent gives to assure a control of quality, so that inferior material will not be sold by concerns who may be irresponsible and may cause serious damage to patients. I know it is not the opinion of the Calco Chemical Company that patents should not be used for controlling quality. We believe they should. Of course, it is theoretically possible that a system of control of quality may be set up so unreasonable that it makes practical production of a particular drug impossible. There is no remedy or no instrument which cannot be misused, but I think the cases in which that would arise would be in so small a minority as to be unimportant in comparison with the great good that can be effected by the control of quality in things which are dealing with human welfare and human life. As far as the whispering campaign is concerned, I think my company and my own views are that even if Dr. and Mrs. Dick did get some revenue from it, we would be the last to feel that that is a serious reflection. That is something they have to decide on the basis of their own conscience and on the basis of the rules and practice which are laid down by the American Medical Association, with whom they are affiliated. Mr. Hutchison made one statement in his recommendations which I think may be due to a greater familiarity with the Canadian patent act than with the United States patent law. I should like to comment on that as a patent attorney. In his recommendation, he recommended that no medical patent be granted on a substance, that patents be granted only on processes or a particular process of making it. If a patent is to be considered as a good thing for the process in order to control quality, in order to stimulate the production, then it is just as important that there be control of the product, where that product is new, which control is possible under the United States patent practice. If you do not have that control, there is nothing to prevent the development of other processes which may be inferior and which may result in putting on the market material which is inferior and which may have the serious consequences Dr. Dick has brought out.

MR. WILLIAM T. MIDDLEBROOK (University of Minnesota), Minneapolis: As I understood you, Mr. Hutchison, you stated, on the basis of your experience, that no fee should be paid to the inventor. I wonder if you won't elaborate on that just a bit.

DR. J. C. MORRELL (Universal Oil Products Company), Chicago: I was somewhat amazed at Mr. Unger's remark that he couldn't do further research on the subject matter of a patent, and then the next speaker's remarks that they hold no restrictions on further research in respect of patents which his company owns. I think if Mr. Unger would consult an attorney he would find, practically speaking, that the holder of a patent can hold no restrictions. He has the right only to prevent the use of the product or the process or the apparatus of the patent, as claimed, so that research will not in any way be hurt by the issuance of patents. I represent a company

that is a research and patent licensing organization. We have some 1,100 patents. I am interested somewhat in the mechanics of obtaining patents on medicinals or pharmaceuticals for human consumption, and that would also include foods, particularly as it concerns the public. The test of an invention is novelty and also utility, i.e. whether a thing is new and useful. Opposed to the question of whether a thing is useful is the question as to whether a thing may be harmful. Certainly, if a thing is harmful it can't be useful. So the patent examiner has that problem to decide in connection with the issuance of a medical patent. Most of the so-called patent medicines, I dare say, are not patented. They are mixtures, perhaps, of materials which have the same functions in admixture as the individual materials, which functions may be well known, and from that point of view there are certain restrictions in the issuance of patents which are self regulating. I believe that if the question of patents becomes general for the medical profession there might be several precautions set up for the protection of the public. One, for example, is that an inventor should make affidavit, perhaps witnessed and confirmed by competent witnesses, that what he claims is so and that the product of his patent is not harmful. Many patents, as a matter of fact, have claims which cannot be confirmed, certainly in their entirety. Secondly, it might be desirable for a recognized association like the American Medical Association to have an advisory body which would assist the Patent Office in passing on the novelty and utility of the products of medical patents from the aspect of their harmlessness; that is, to certify that they will not be harmful to the public. Thirdly, we may have restrictions such as those set up by the pure food and drug act and also certain controls and restrictions which may be set up by administrative committees selected to protect the public. I believe that the physician is entitled to the benefits of new discoveries and inventions, and he should be rewarded in the same way as any other inventor; that such reward not only stimulates further research, but it puts a premium on the genius who has done something good for humanity and is permitted and helped to go forward and continue to do that good by suitable monetary reward, subject of course to the necessary restrictions for the public benefit.

DR. ESMOND R. LONG (National Research Council), Washington, D. C.: I shall limit my remarks to the actions and policies of the National Research Council. I am afraid you will feel that the council in its consideration of medical patents is much less wise than the groups whose views have been presented to you this morning, because the Division of Medical Sciences of the National Research Council has never been able to agree on a policy and follow it consistently through the years since its organization. The policy originally adopted by the National Research Council following action by its executive board Feb. 13, 1924, was expressed as follows: "Moved, That, in the event patentable discoveries are made in the course of work carried on under the auspices of the National Research Council, it is expected that the Fellows or others, on the approval of the Research Council, which will defray the cost, will apply for patents on such discoveries as should be protected in the interests of the public, and that such patents will be assigned to the National Research Council; and, further, that the National Research Council hereby declares its intention to dedicate to the use of the public, in such manner as the Research Council may deem most effective, the results of such discoveries as are made in the course of investigations conducted under the auspices of the Research Council." In the succeeding fifteen years the Research Council has held to that ideal of dedication to the use of the public. In actual practice, however, patents have been secured by Fellows of the Research Council and investigators working under grants from the Research Council and have been disposed of in various ways, including university administration. In general, I would say that the actions taken by these investigators which were officially approved by the Division of Medical Sciences, but chiefly as a matter of convenience, have not been with the wholehearted endorsement of the division. On Nov. 11, 1933, this extremely brief motion was passed by the Division of

Medical Sciences, although not by unanimous vote: "Moved, That the Executive Committee, Division of Medical Sciences, National Research Council, is of the opinion that in general the patenting of biological methods or products, especially as applied to medicine and public health, is detrimental to the best interests of science and the public." I should say, however, that since then a number of patents have been taken out under the auspices of the council, particularly by one group operating under the Division of Medical Sciences, namely the Committee on Drug Addiction. Their problem in general has been simpler, because most of the important new substances discovered have narcotic action, and narcotics are covered by law. I should say first that twelve years after the first formulation of policy by the National Research Council, i.e. in 1936, a restatement of policy was made, reading as follows: "In the event that patentable discoveries are made in the course of work carried on under auspices of the National Research Council by Fellows of the Council, or by collaborators in special research projects sponsored by the Council, or by recipients of grants in aid of research from the Council, it is expected that the discoverer will notify the Council of these results in order that the Council may take such steps as may seem advisable to protect the interests of the public in the matter." In other words, the statement called for individual consideration of each question. It continued: "In view of its responsibilities for the administration of funds of a public trust nature, the National Research Council hereby declares its intention to conserve for the use of the public, without profit to the Council, and in such manner as the Council may deem most effective in each case, the results of such discoveries and inventions as may be made in the course of investigations conducted under the auspices of the Council." By far the largest number of patents taken out under the auspices of the Division of Medical Sciences of the National Research Council have originated in the council's investigation in the field of drug addiction. Numerous substances, both with and without narcotic action, have been discovered by the investigators operating with funds administered by the council in this field. Narcotic drugs naturally called for special consideration. Action was taken in December 1936 by which certain narcotic drugs were transferred to the Secretary of the Treasury, as follows: "Voted, that the Administrative Committee approves the application by Dr. Lyndon F. Small for a patent covering the production of dihydrodesotymorphine-D developed in the course of his investigations carried on under the direction and with the financial support of the Committee on Drug Addiction of the Division of Medical Sciences and the assignment of such patent to the Secretary of the Treasury under terms to be approved by a legal adviser of the National Research Council or counsel of the Treasury, and that the matter be referred to the Council of the National Academy of Sciences for its approval." The course thus approved has been followed in the case of several narcotic drugs discovered by Dr. Small and his colleagues. For non-narcotic drugs in the morphine series, the following mechanism has been adopted and followed up to the present time. It is purely under trial. I am not stating that it will be the policy of the council in the future. I simply leave it with you as a thought and a method which the National Research Council has explored. Action in this field was as follows: "Voted, that the National Research Council recommends to the Council of the National Academy of Sciences that it approve that the patentee of nuclear alkylated, aralkylated and arylated derivatives of the morphine series, developed through investigations supported by the Committee on Drug Addiction of the Division of Medical Sciences, assign his patents to the Research Corporation for the handling of these substances in other countries than the United States; and, further, that as additional patentable substances may be developed in the work of the Committee on Drug Addiction, the committee be authorized to initiate negotiations for transferring to the government of the United States the patents on all those substances which come under the control of the narcotic or other federal laws, and for other substances to initiate negotiations with the Research Corporation or any

other qualified agency looking to the ultimate transfer of the council's patent rights on those substances to the corporation or other agency, subject in each instance to final approval of the National Research Council and the National Academy of Sciences." In brief, the Division of Medical Sciences of the National Research Council has countenanced three procedures: It has approved certain patents dedicated to the public benefit under systems like those discussed today; secondly, on its own initiative it has assigned certain patents to the United States government; finally, it is exploring the possibilities of utilizing a nonprofit organization, the Research Corporation, for certain products developed as a result of research under its auspices.

DR. L. G. MAISON (Gane and Ingram, Inc.), New York: So far, this entire discussion has appeared as a defense mechanism on the part of the scientific medical body developing patents against the attitude of the pharmaceutical manufacturer. Since I am here on behalf of a manufacturer, I should like to hear the other side of the story, learn something of the attitude of the medical profession toward the manufacturer who issues a patent, enforces that patent and derives a high price for the medication covered by that patent. As an example, I mention a patent on one substance which sold for \$60 a pound during the life of the patent, but which, after the expiration of the patent, was available in the open market for \$2 a pound. I refer to phenobarbital. I should also like to learn something about another phase of patented medical substances; namely, where a university obtains a patent and enforces it primarily for the collection of royalties, although no control of manufacture may be involved with the substance patented. I refer to the copper and iron patent, regarding which Dr. Fishbein commented in the editorial columns of THE JOURNAL to the effect that it was a rather amazing situation for a distinguished university to collect royalties on a patent so contestable from a scientific point of view. Also I should like to have some expression or gain some experience here as to what the manufacturer is to do who develops a new medication, patents it and manufactures it exclusively, and how the medical profession reacts to the price placed on such preparations.

DR. DAVID T. SMITH (Duke University), Durham, N. C.: Dr. Dick mentioned the whispering campaign. I want to mention another phase of the whispering campaign, to the effect that under the rights given by the patent severe restrictions are placed on research in other institutions with regard to streptococcus antitoxin. It is only fair to Dr. Dick that she be allowed to deny this and clear herself before this group.

MR. JOHN UNGER, Pittsburgh: The two gentlemen who have discussed my remarks previously have intimated that patent rights do not include such things as inhibiting one from publishing on research matters, whereas Dr. Dick in her presentation, I believe, told us that patent rights cover literature. The point I want to make is that I myself consulted this man who holds the patent on this procedure, and he advised me I could not publish it without his consent. I have no legal advice, and I am not a legal expert. I do not know how the situation stands.

MR. F. LORNE HUTCHISON, Toronto: In response to Mr. Norton, I assure him that I am more familiar with the United States Patent Act than I would like to be. I wonder if he is familiar with the fact that the United States is one of the few leading countries in the world which do not already have particular restrictions relating to patents that affect medicine or food. Mr. Norton is a patent attorney. I have no doubt that he is for patents. Well, I am too, to a degree. I am for their uses, because I think they have very real good uses. I am very much opposed to their abuses, and I feel that they have sometimes been and are bound sometimes to be abused in connection with things that so intimately affect the public health—medicines and food. Mr. Norton, if you and your confrères don't take some sort of action to evolve reasonable restrictions I would suggest that it won't be long before in the United States there may be no patents relating to medicines. But I do not suggest those sections I read from the Canadian patent act as particularly good. I simply suggested them to you as the sort of thing that might well be considered.

Mr. Middlebrook, I think it would not merit the time of this meeting to have a long discussion on the subject of rewards to the noncommercial inventor. I happen to be fundamentally, or I used to be, a biochemist. If I were a practicing biochemist, had a laboratory or an office down the street here, and took out a patent, naturally I would expect to derive profit from it, whether I issued licenses under the patent myself or whether I sold the patent to a commercial manufacturer or licensed a number of commercial manufacturers. But if I am on the staff of a university I am not satisfied that it is desirable, either from the university's point of view or from my point of view, that I get a "cut" on any moneys received by the university in respect of patents on inventions made in the university, with the aid of university facilities and time. A good deal of literature on this particular subject has been published. That is one of the reasons for my thinking that discussion of this subject would not merit the time of this meeting. I read yesterday, as a matter of fact, a considerable number of publications wherein the pros and cons of this very thing are advanced. I can give references to those publications to you or any one else who is interested. There you can see these pros and cons. Meanwhile all I have to say to you is that I happen to be on the side of those who feel it is undesirable, unless necessary, that a man in a university who applies for a patent gets a "cut" from any proceeds which accrue from the patent.

DR. GLADYS H. DICK, Chicago: Two of those who have spoken have mentioned subjects that concern the Scarlet Fever Committee. One suggested that we might have been in error in concluding that some of the commercial manufacturers are opposed to patents for the control of quality. This was not our conclusion; it was what they told us. In reply to Dr. Smith's question, Dr. Smith must know that important research on all antitoxins, including scarlet fever antitoxin, was carried on in his own university without any interference by the Scarlet Fever Committee. The Scarlet Fever Committee is glad the work was done, since it resulted in improvement of scarlet fever antitoxin. The investigator patented his own work, also without any interference from the Scarlet Fever Committee, and the Lederle Laboratories, a licensee of the Scarlet Fever Committee, is manufacturing under the patent on this improvement.

A MANUFACTURER'S VIEW OF MEDICAL PATENTS IN RELATION TO THE PUBLIC WELFARE

JOHN F. ANDERSON, M.D.
Vice President, E. R. Squibb & Sons
New York

In summoning a national conference on medical patents, the Board of Trustees of the American Medical Association exemplifies a trend that has become increasingly manifest in recent years. I refer to the tendency of the public, the medical profession and the federal government not merely to hope for improvement of the public health but rather to give the movement direction by critically examining and improving the social instrumentalities involved. As some philosopher once so rightly said, "Progress may need nudging now and then." So, medical patents, which have been, I believe, an instrument of progress, should be examined anew from time to time that we may evaluate their virtues and faults and prescribe effective remedies when indicated to be necessary or desirable.

From the tenor of my invitation I judge that I am expected to consider medical patents in relation to the public welfare from the point of view of the manufacturer. I trust that no one will be disappointed if I say at the outset that to me the manufacturer's point of view does not exist as a wholly detached entity. Like so many of those occupying executive positions in the drug industry, in the course of years, I have acted for long periods in each of a variety of capacities. Some of them have been concurrent. In my case, I have served, among other capacities, as a practicing physician, an administrator of a federal health agency, and a director of biologic-pharmaceutic

research. In consequence, I believe that my outlook, like that of so many of my colleagues, is free from marked bias in favor of the attitude of any one special-interest group. And the opinions I shall express, though I believe them to be sound in the premises, are held with more scientific tentativeness than dogmatic assurance.

As you know, our patent law stems from our constitutional provision empowering Congress "to promote the progress of science and the useful arts by securing for limited times to authors and inventors the exclusive right to their writings and discoveries." In return for the right to exclude all others from the practice of his invention for seventeen years, the patentee gives to the public a full disclosure of the invention. This the public may use gratis after that period has expired. If, on the other hand, an inventor elects to keep his invention secret, he loses his exclusive property in it as soon as it does become known. But secrecy, as long as it is maintained, may not only hamper utilization of the invention but also impede research by others in the process of continued progress.

A "terminological inexactitude" of seeming obscure origin is the so-called patent medicine, applied to a proprietary preparation the formula of which is not revealed. Since "patent" means "open," a disclosure is the chief prerequisite to the issuance of a patent, so that "patent medicine," far from being synonymous with "patented medicine" is a glaring misnomer. A hostile attitude toward medical patents may be traced in the minds of some to this false association of origin. For others, it may proceed from the fact that only a few decades ago a considerable number of our medical patents were of the type of old wives' remedies. I have in mind also the chant of the second witch in Macbeth:

Fillet of a fenny snake
In the cauldron boil and bake;
Eye of newt, and toe of frog,
Wool of bat, and tongue of dog,
Adder's fork, and blind worm's sting,
Lizard's leg, owl's wing,
For a charm of powerful trouble,
Like a hell-broth boil and bubble.

Whatever may be the historical associations, today few if any patents are granted on materials of such indefensible types. They are not even to be related to compositions on the same plane of invention as physicians' routine prescriptions. As bearing on present practice, it is to be observed that about half of the preparations listed in the 1938 edition of *New and Nonofficial Remedies* have been or are covered by patents or pending applications. Instances do occur, however, when the Patent Office examiner is technically obliged to issue a patent on some possibly unworthy subject matter. An example would be the case of a biologic cancer treatment. In such cases, however, the examiner is most likely to be subjected to a severe and most effective barrage of criticism from the medical profession.

Patents were created to promote the public welfare. We may not and should not discount the intellectual pleasure of solving problems and the desire to merit the favorable regard of one's fellows as stimuli in the field of invention. Nor should we overlook the important influence of the prospect of material gain. I do not mean to decry the average human being as mercenary. On the contrary, he would be scarcely normal if he lacked the impulse to procure for himself and his dependents the opportunities, necessities, and even those luxuries requisite to well being, a well rounded life and more than bare security in old age. A patent is such a stimulus to persistent effort and in the long run the public is served through disclosure of the results obtained.

If with respect to inventions generally such motivation is desirable, isn't it apparent how even more essential it is that society should provide at least as great an incentive in connection with inventions of exceptional human value? This is particularly true with those in the field of treating human ailments, alleviating pain and prevention of disease, the toll of which on our national income has at times assumed staggering proportions.

I am one of those many enthusiasts who do not hesitate to assert that our patent system has been an essential factor in transforming our wilderness of only 300 years ago into the world's richest nation, with a standard of living unequaled elsewhere. If it has done so much, how much more may it yet accomplish. I agree that our mineral and agricultural resources under a system of free enterprise had much to do with the extraordinary growth of our industries, but our patent system, with its incentives and rewards, has been a major impelling force.

This assertion finds support in the relatively recent experience of two foreign states. The Netherlands discontinued its patent system in 1869. A great decline in its industrial development followed until 1912, when the patent system was restored. The Soviet Union, though operating on principles diametrically opposed to our individualistic, capitalistic order, is reliably reported to have enacted somewhat recently patent laws that are fundamentally similar to those of the other Western powers. Added significance attaches to these instances when it is considered that in the absence of patent laws in those countries their citizens and the nations themselves would still have had access to all the published inventions of the rest of the world, without granting any compensatory monopoly therefor. Nevertheless, they decided that the advantages of such a situation were not as great as those flowing from patent systems of their own. Let me cite still another corroborating sidelight. Our law imposes no restrictions on medical patents, whereas France will not grant patents on medicines at all, and Great Britain and Germany (and most other European countries) grant medical patents only if limited to the specific processes of manufacture. As a result, the temptation to keep medicines secret should be made greater in those foreign countries than here. This is borne out by the wider use of proprietary medicines in England and France, which I am informed is readily noticeable.

You may inquire whether this need for incentive and material reward applies to the many instances in which the inventor does not himself commercialize the invention but assigns it to a corporation or a university. I think that it does apply, for the reward in such cases is merely transmuted into a form more acceptable to the inventor, usually either as a fixed sum or as a regular salary. The employee basis, perhaps the one that obtains with respect to most medical patents, assures the inventor of a relatively steady income, during fallow as well as productive periods. This is in itself a continuing incentive. It helps to keep the fires of inventive genius burning. Then too, trained scientific investigators are saved the burdens of the problems entailed in commercialization of their inventions, by no means negligible. For want of training and experience in such operations, and lacking the necessary equipment and capital, most inventors would be unlikely to do the work well or efficiently, except at great sacrifice of time and money. They are not diverted from the research for which they are qualified. It seems a fitting division of labor that the inventor should turn the commercialization aspect over (as by assignment) to an organization specializing therein. It is in the public welfare thus to enable university workers, after making inventions, to leave the administration of the patents with its contractual, litigative and general business aspects to commissions, committees or corporations created for the purpose. It has been found that such organizations in turn can make for the fullest distribution of the product while minimizing the heavy cost of performing necessary assays, supervising literature and other control operations, by issuing nonexclusive licenses to a limited number of manufacturers of demonstrated competence and integrity.

Now let me stress a note of warning. An individual who, resolved not to profit by his investigations, publishes a complete account of his work but refrains from patenting it, may fall short of serving the public welfare to the fullest degree. For the Patent Office, having no official knowledge of his priority, may grant to some other person a patent on the same subject matter. As you know, citations of the publication are surmountable by the simple expedient of filing an affidavit

alleging an earlier date, supported by undated evidentiary material. In that event the true inventor's generosity will have been in vain, and not only the public at large but even he (unless he is prepared to enter into costly litigation) may be barred from the practice of the invention. Accordingly, the inventor would be best advised to secure a patent and then, if he prefers, either dedicate it to the public or, more effectively, assign it to some group or institution qualified to promote and administer it.

In our science-conscious civilization, none would be likely to question the desirability of a constant and ample supply of funds for medical research. Necessary funds are not always forthcoming when most needed, if at all, and then only intermittently or meagerly, since they are frequently dependent on the caprice or varying resources of private benefactors. Patents, on the other hand, by laying the foundation for a steady income, enable universities, institutions and individuals to maintain continuing research schedules on a self-supporting basis, free from unfortunate restrictions, however well intended. Some universities do not permit members of their staffs to take out patents. Others dedicate their patents to the public. A third group, whose policy appears most likely to survive, is the one which, through the medium of a committee or special nonprofit corporation, exchanges licenses for royalties, takes from the proceeds so realized a minor portion to reward the inventor and to meet expenses, and devotes the remainder to research. Society reaps the advantage, pays the price and so paves the way for further attainments, which serve it most in the final analysis.

I have already mentioned that mere publication of an invention may not be in the best interests of the public welfare. A related factor is also to be observed. As published, the results of medical research work are frequently not in a condition for immediate utilization. Much developmental work may have to be done, and extensive chemical, pharmacologic and clinical studies may have to be conducted before the efficacy, safety and limitations of the product are so fully determined as to justify its broad distribution and sale. In the face of the expense and precariousness of advancing a desirable product to the commercial stage, and thereafter of promoting it so as to overcome the cautious resistance to any new product, may we not respect the reluctance or refusal of the manufacturer to embark on such a project unless he is protected by patent licenses against unburdened, destructive competition? It follows that, in consequence of failure to patent it, the invention—though ostensibly to be had for the mere taking—may actually never become available to the public at all.

Let me discuss the role of the manufacturer more concretely. In our times the heart of any large drug manufacturing company is its research department. No company can long hold a preeminence in its field or endure without an adequate research department. Such a department requires men and women of outstanding skill and scientific aptitude. Companies search the world over to obtain them. They must be provided with adequate facilities and materials and be given free opportunity to pursue the directions their talents take. Months and even years of apparently fruitless efforts may be consumed before a useful achievement is forthcoming. The expense of this personnel and these operations must come out of either capital or earnings of the manufacturer. The achievement of this combination of personnel, facilities and materials afforded must then be adequately tested and marketed. If successfully marketed, the manufacturer recoups his capital and earnings expended.

Then there is the inventor. How frequently we observe him coming to the manufacturer after enduring countless privations, having exhausted his own savings and frequently those of his friends and others who believe in him, in a futile effort to obtain sufficient understanding of his invention to enable its economical manufacture and distribution. Under such circumstances, manufacturers are constantly lending their resources to inventors, only in the majority of cases to find on their investigation, and after the expenditure of considerable funds, that the product or process is too unpractical to permit its use

and distribution. Fortunately, on a sufficient number of occasions the product proves susceptible of development and practical application. Losses are recouped, resources are strengthened and the manufacturer and inventor are enabled to undertake further achievements where otherwise insolvency or strangulation of research would follow. This has been the road of progress. I submit that this road will be forever blocked by any measures which deprive the inventor and the manufacturer of the opportunity to profit from the patent protection now obtainable. Surely that would not be for the public welfare.

Another way in which medical patents operate for the common good is in making possible control with respect to the manner of commercializing the invention. The patentee can contract with reputable and competent organizations and, by suitable provisions in the license, can dictate the conditions of manufacture, distribution and sale so as to forestall misrepresentation and extortion or failure in operation. He can assure a moderate price and high and uniform quality (and thus prevent the marketing of inferior preparations by which the invention might be irreparably discredited). These things he usually does in his own self interest, if for no better reasons.

In this connection it must be remembered that the licensor, especially the university foundation or other quasipublic institution, has a social interest when framing the license provisions. The establishment of fair and reasonable, perhaps even uniform, prices and other controls seem proper subjects for stipulation. Any prohibitions against research looking toward improvement of the product or against the development of other products having the same therapeutic uses seem undesirable as contrary to the public welfare.

It might be possible to regard with comparative equanimity a patentee who refused to place on sale, or to allow any one else to market, a mechanical device covered by his patent; but few of us could or would maintain the same philosophical calm with respect to the similar handling of an invention calculated to save lives or mitigate suffering. In other words, suppression of medical patents would be intolerable. While no instance of such suppression is known to me, I believe we should eliminate any such possibility by the preparation and adoption of legislation drafted to the effect that if the patentee does not within a reasonable time (to be judged by the particular circumstances of the case) himself make or enable others under appropriate license to make the article available to the public in adequate quantity and high quality, others may, for a suitable royalty payable to him, procure the right to do so.

In conclusion it appears appropriate that I review in a few words what seem to me the most important considerations respecting the importance of medical patents, which take into account the interests of the inventor, the public, the medical profession and the manufacturer.

Patents on medical discoveries, operating under our present system, offer far more benefits to the public and the other groups concerned than that of any other system and require their continuance. This has been demonstrated by comparison with conditions in other countries and a consideration of what might occur in this country were there no legal protection of inventors. The truth of this statement is believed to be evident because of the following considerations:

1. The incentive to the inventor is promoted by a reward which can arise only if the invention is useful for the alleviation of pain or the treatment of disease.
2. Obviously then a great social benefit arises if this incentive is preserved.
3. Inventions become increasingly more difficult as medical science increases in perplexity. Consequently, the cost of invention in terms of research has risen enormously and derives much of its support from licenses for the use of the patent. Therefore, continued research is essential to the development of new products of medical usefulness and can be supported only if the previous legalization of the inventor's exclusive right is maintained.

(To be continued)

THE WAGNER HEALTH BILL AND SOME NEW DEVELOPMENTS

Hearings on the Wagner Health Bill, S. 1620, before the subcommittee of the Senate Committee on Education and Labor, were concluded, as far as the present session of Congress is concerned, on July 13. Representatives of osteopathy who appeared before the committee carefully refrained from defining osteopathy or distinguishing it from the practice of medicine. They asked that the bill be amended to entitle a licensed osteopath to render service under the act within the limits of his license. If the bill should be so amended, they said, it would meet with their approval. In view of the impending adjournment of Congress, authorities agree that the bill cannot run the gantlet of subcommittee and committee and be reported to the Senate before the next session of Congress.

Efforts have been made to accomplish some of the objectives of the Wagner Bill through amendments to another bill, H. R. 6635, which now has passed the House and Senate. One amendment proposes to authorize increased appropriations for the Children's Bureau to enable it to enlarge its services for maternal and child health services and for crippled children. Another amendment proposes to increase the appropriation authorized by the Social Security Act for the enlargement of the work of the Public Health Service. A third, proposed by Senator Wagner, was designed to authorize the Social Security Board to set up a federal, nationwide medical service for persons who are unemployed because of their own disabilities.

The Senate Committee on Finance, having under consideration H. R. 6635, reported favorably on the amendments proposing to authorize increased appropriations for the Children's Bureau and for the Public Health Service and these amendments were accepted by the Senate.

Senator Wagner's amendment proposing to authorize the Social Security Board to set up a federal nationwide medical service for the benefit of persons who may be unemployed because of their physical disabilities was not adopted by the Senate Committee on Finance or called up by Senator Wagner when the bill was being debated on the floor of the Senate. Senator Wagner proposed another amendment providing for the

creation of an Advisory Council on Disability Insurance, which amendment was accepted by the Senate. The proposed council would be established by two independent Congressional committees, the Committee on Finance of the Senate and the Committee on Ways and Means of the House of Representatives, each "in cooperation with the Social Security Board." The amendment does not limit the membership of the proposed council and the qualifications of its members are not defined. They are to be appointed, however, as representatives of employers, employees and the general public. Provision is not made for the representation of the medical profession on the proposed council. The Senate Committee on Finance and the Committee on Ways and Means of the House of Representatives are to be permitted to make appointments to the Advisory Council on Disability Insurance only "in cooperation with the Social Security Board," and all necessary technical assistance is to be furnished by that board.

Specifically, the proposed council is to study and to report on the establishment of disability benefits under the Social Security Act as amended, with particular reference to the relationship of disability insurance to other forms of social insurance, the scope and coverage of disability insurance, the qualifications necessary to entitle a person to the benefits of disability insurance, the coordination of disability insurance with relief and other programs for alleviating distress among the disabled, rehabilitation services and any other matters that the Social Security Board or the Senate Committee on Finance or the House of Representatives Committee on Ways and Means may deem relevant to the inquiry.

The bill to which these amendments were appended was passed by the Senate July 13. The House of Representatives refused to accept the Senate amendments and the bill was referred to a conference committee, which will endeavor to adjust the differences between the bill as passed by the House and the bill as passed by the Senate. The amendments discussed will come before this committee for adjustment, since they were not in the bill as it passed the House.

GRADUATE MEDICAL EDUCATION

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

MARYLAND

In the winter of 1886 Dr. W. H. Welch began a series of postgraduate lectures for the physicians of Baltimore. These were given in the laboratory of the department of biology of the Johns Hopkins University during the period in which Johns Hopkins Hospital was under construction. There were nine lectures in the first series devoted to a consideration of micro-organisms in disease. The following autumn systematic courses in bacteriology and pathology were offered. These constituted the first formal medical courses given in the university. This program was continued regularly until 1889, when the hospital opened, and from then on clinical subjects were included.

During the year 1889-1890 the instruction was given at the hospital in pathology and bacteriology as well as in medicine, surgery, gynecology, hygiene and psychiatry. Lectures, demonstrations, laboratory courses and bedside and clinical teaching were attempted in the new laboratories, wards, dispensary, amphitheater and private operating rooms of the hospital. Opportunities were afforded only to graduates in medicine for practical clinical instruction, which included daily visits and case studies with Dr. William Osler. Physicians were admitted to all of these courses extending throughout the academic year for a fee of \$100. Fees for individual courses were \$25.

In 1890 and 1891 similar instruction was offered. Medical graduates who attended only the didactic lectures paid proportionate fees. Those residing in Baltimore were admitted without charge. Actually this was largely undergraduate instruction. The courses continued until 1893, when undergraduate students were first admitted. By 1896-1897, when these students had reached the wards and dispensary of the hospital, there

were insufficient faculty and facilities to continue instruction for graduates during the academic year. The courses were then given during May, June and July but soon were discontinued, and, except for sporadic efforts during two or three years after the World War, they have not been resumed.

In 1922 a committee of the faculty of the medical school of Johns Hopkins University considered the advisability of giving refresher courses for medical graduates. The committee was unwilling to engage in such instruction but offered in its place opportunities for qualified physicians to study over six months or longer periods in the various departments of the medical school. Tuition of \$50 was charged.

During 1936-1937 the school's committee on postgraduate instruction again considered the policy of the university in connection with graduate teaching in view of the training requirements of the various specialty boards and no change in policy was recommended. Participation by the school in the syphilis program of the United States Public Health Service expanded the interest of the institution in graduate training. Facilities were provided for the instruction of public health personnel with the aid of federal funds and with the aid of a member of the staff of the Rockefeller Foundation. This has brought about a substantial increase in the number of graduate physicians registering as students.

In 1937-1938 twenty-four physicians registered as postgraduate students, and in that year the department of the history of medicine initiated "A Graduate Week in Medical History." The week was planned to bring together persons interested in medical history. Thirty-four registered for this program. During April 1939 a second graduate week in medical history was given.

The School of Hygiene and Public Health of Johns Hopkins University offers unique opportunities to physicians interested in public health to continue their training, especially in syphilis, epidemiology and biometrics. On recommendation of their state health officers, medical graduates may spend an academic year in the school of hygiene, in which half of the course may be elected in the medical school, including clinical training in such subjects as pediatrics and diseases of the heart. The enrolment now averages seventy graduate students each year.

In 1924 the University of Maryland School of Medicine began an eighteen day intensive general course for practicing physicians. Opportunities were afforded those who desired to study the methods of diagnosis and treatment currently used in the university clinics. Registration was limited to twenty. Maryland physicians were charged \$25 and out of state physicians \$50 for the course.

After 1924 instruction in general medicine and surgery was discontinued and postgraduate seminars in pediatrics were begun. These were designed for physicians in general practice and were arranged so that local physicians might attend only morning sessions and continue their practice in the afternoons. Clinics, bedside rounds, instruction in laboratory methods and clinical pathologic and radiologic conferences were included. A registration fee of \$50 was charged.

A postgraduate seminar in diseases of the cardiovascular system has been offered also with instruction in pathology, electrocardiography, roentgenology, clinical studies and therapy. A fee of \$100 was charged and enrolment was limited.

A conference on tumors is held at weekly intervals at the University Hospital by members of the Oncological Clinic of the University of Maryland. Patients and pathologic material are shown and radiologic and surgical problems are discussed. These conferences are open to practicing physicians.

In cooperation with the American College of Physicians, the schools of medicine of the University of Maryland and of the Johns Hopkins University provided faculty and facilities for

two week postgraduate courses in general medicine and cardiovascular and respiratory diseases during March 1939. Fifty-one physicians registered for the former and sixteen for the latter course. A symposium on a different subject was held each day beginning with the basic sciences and extending into clinical medicine. In the course in cardiovascular and respiratory disease there were greater opportunities for those who attended to examine patients.

Since it is believed that approximately one third of the physicians practicing in Baltimore are connected with the two medical schools, it is apparent that weekly faculty conferences and other school activities provide ample opportunities for continuing medical education. Furthermore, approximately three fourths of the physicians practicing in Maryland are within easy reach of the city and the medical educational facilities it provides.

The Cancer Committee of the Medical and Chirurgical Faculty of the State of Maryland has offered instruction in cancer to any county society in the state on request.

The joint committee on maternal mortality with representatives from the State of Maryland Department of Health, the Baltimore City Medical Society and the two medical schools are analyzing all maternal deaths occurring in Baltimore. This committee meets each month. The meetings are open to practicing physicians. The state society's committee on maternal and child welfare has offered its services to county medical societies of the state to discuss the problems of obstetric and pediatric practice. Dr. Louis H. Douglas is chairman of this committee.

The state department of health conducts case finding clinics in tuberculosis and syphilis and antepartum clinics which are attended in the main by local practicing physicians. Consultants from the health department offer their services for educational programs.

There are 2,821 physicians licensed in the state of Maryland, 1,434 of whom are members of the Medical and Chirurgical Faculty of the State of Maryland.

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—H. R. 2296, proposing to restore certain benefits to World War veterans suffering from paralysis, paresis or blindness, or who are helpless or bedridden, without regard to misconduct, has passed the Senate with amendments and the Senate amendments have been agreed to by the House. H. R. 5452, to provide certain benefits for World War veterans and their dependents, was amended in the Senate so as to provide hospital and domiciliary care, on a parity with other veterans, for retired officers and enlisted men of the Army, Navy and Marine Corps, and the Coast Guard who served during a war period. This amendment has been accepted by the House.

Bills Introduced.—S. J. Res. 169, introduced by Senator Smith, South Carolina, proposes to direct the Commissioner of Public Works, out of any funds available to the Public Works Administration, to pay to the following hospitals the amount specified as federal grants "representing 30 per centum of the cost of the self-liquidating projects heretofore undertaken by such hospitals with money loaned by the Federal Emergency Administration of Public Works": Allegheny General Hospital, Pittsburgh, \$540,000; Community Hospital Association, Battle Creek, Mich., \$60,000; Frances Mahon Deaconess Hospital, Glasgow, Mont., \$37,000; Franklin Square Hospital, Baltimore, \$52,000; Greene County General Hospital, Waynesburg, Pa., \$21,000; Huron Road Hospital, East Cleveland, Ohio, \$101,000; Jewish Memorial Hospital, New York, \$105,000; McLeod Infirmary, Florence, S. C., \$90,000; Public Health Association, Tulsa, Okla., \$4,000; Robert Packer Hospital, Sayre, Pa., \$136,000, and Weymouth Hospital, South Weymouth, Mass., \$18,000. If the funds available to the Public Works Administration are not sufficient to enable the commissioner to make the payments authorized, there is to be appropriated such sums as may be necessary. H. R. 7165, introduced by Representative Lea, California, proposes to authorize an appropriation of \$1,500,000 to construct in north-

western California a 300 bed capacity veterans' hospital for the accommodation of veterans suffering from general medical and surgical disabilities.

DISTRICT OF COLUMBIA

Bills Introduced.—S. 2776, introduced by Senator King, Utah, and H. R. 7095, introduced by Representative Kennedy, Maryland, propose to provide for the reorganization of the local government in the District of Columbia. Among other things, the bills propose to transfer to a Department of Personnel the functions now exercised by the Commission on Licensure to Practice the Healing Art and by such examining boards as exist by appointment of that commission, including the Board of Examiners in the Basic Sciences and the Board of Examiners in Medicine and Osteopathy. S. 2777, introduced by Senator King, Utah, and H. R. 7155, introduced by Representative Randolph, West Virginia, propose to amend the act providing for insanity proceedings in the District of Columbia so as to provide (1) for the transfer from Gallinger Municipal Hospital to Saint Elizabeths Hospital of persons of unsound mind who are so disturbed, excited or violent, or who manifest homicidal or other dangerous tendencies, that they may not be properly cared for at the former hospital; (2) that a judge may commit an insane person to the custody of the Veterans' Administration for care and treatment in a Veterans' Administration facility, if there has been filed a certificate issued by the Administrator of Veterans' Affairs showing that such certain insane person is entitled to such care and treatment and that facilities therefore are available. S. 2779, introduced by Senator King, Utah, proposes to eliminate from the healing arts practice act of the District of Columbia the requirement that examinations be held on the second Monday in January and July of each year and to provide that such examinations may be held at such times as the Commission on Licensure to Practice the Healing Art may by rule or by special order determine.

WOMAN'S AUXILIARY

PRESIDENT'S ADDRESS

At the St. Louis meeting, Mrs. Rollo K. Packard, Chicago, incoming president of the Auxiliary to the American Medical Association, said: "We, interested in medical care, do not believe that radical changes in the methods of rendering medical service have improved such service where they have been tried. We are quite sure that, of all the developments of science, the development of medicine stands out almost alone as the one that has constantly aided mankind. . . . Our chief function is to keep informed of plans, their successes and failures, and to function chiefly in the role of public relations and education, to the end that the public may know of the outstanding accomplishments of the medical profession and science, of the exact facts of our present state of health, of the necessity of preserving the basic principles of our present methods of practice and the importance of the people saving and budgeting as is necessary to meet their medical needs."

Minnesota

The auxiliary to the Hennepin County Medical Society March 10 in Minneapolis was addressed by Dr. Brown of the Child Guidance Clinic of the Minneapolis Public Schools on "Mental Health."

New York

An essay contest for boys and girls, sponsored by the auxiliary to the Medical Society of the County of Jefferson, as its project for the year has as its subject "Highway Hazards." Prizes will be given. The judges are Dr. Harold Gokey, Alexandria Bay, representing the Medical Society of the County of Jefferson; Mr. Lyman L. Goodrich, representing automobile salesmen, and Mr. Alton H. Adams, representing the *Times*.

Dr. Frederick E. Elliott addressed the auxiliary to the Medical Society of the County of Kings in February on medical legislation. Mrs. Dimon Fruchs gave a paper on "The History of Medicine in Brooklyn." The fourth anniversary of

the auxiliary was celebrated at a meeting March 14. The speakers were Dr. Adele Streesean, chairman of the advisory council, and Mrs. John L. Bauer, first president of the Kings County Auxiliary and also first president of the auxiliary to the Medical Society of the State of New York.

Mr. Willard W. Seymour, Syracuse, addressed the auxiliary to the Medical Society of the County of Cayuga in the Auburn City Hospital recently on the blue cross plan for hospital care.

The auxiliary to the Medical Society of the County of Queens met recently. Mr. Dwight Anderson, director, public relations' bureau, Medical Society of the State of New York, explained the difference between the Voluntary Medical Indemnity Expense Insurance and Compulsory Health Insurance. A resolution was passed creating the Carl Boettiger Memorial Fund, named in honor of the late Dr. Boettiger who organized and directed the library of the medical society. The sixth anniversary of the auxiliary to the Medical Society of the County of Queens was celebrated March 17 at the Medical Society Building. At the meeting of the auxiliary March 28 Dr. Bruno Gebhard, technical consultant of the American Museum of Health of the New York World's Fair, told of the Medical Building at the fair and of the exhibits and lectures planned. Mr. G. Starkman, director of exhibits of the New York World's Fair, showed pictures of the many buildings which will be seen at the fair and explained the purpose of each.

The auxiliary to the Medical Society of the County of Rensselaer met at the Troy Hospital recently. Mr. O. T. Anderson, educational director of the community chest campaign, discussed this project. Dr. Joseph Lawrence, executive secretary of the Medical Society of the State of New York, also addressed the auxiliary on the "Legislative Side of Medicine."

The auxiliary to the Medical Society of the County of Schenectady met at Sunnyside Hospital for Crippled Children recently. Miss Laura Lorenson, New York, lecturer on decorative arts, gave a stereopticon lecture on "The Romance of Pottery in Every Time and Every Clime."

MEDICAL ECONOMIC ABSTRACTS

SICKNESS INSURANCE FOR GERMAN MINERS

The number of miners covered by sickness insurance increased 9.37 per cent from 1936 to 1937. Premiums in the German sickness insurance system are a percentage of wages. An increase in wages caused the income of the insurance societies to increase 18.7 per cent and the total income of the insurance carriers increased 15.18 per cent. At the same time the expenditures increased 16.98 per cent, or so much more than the increase in income that the income in 1936 was not sufficient to cover expenditures. Every increase in the number of the insured during 1937 has increased the loss in the insurance system.

The report of the miners' sickness insurance of 1937, which is summarized in the *Deutsches Aerzteblatt* (69:415 [June 2] 1939), explains that this condition is caused by the increase in the number of days of sickness, which was 12.8 per member during 1936 and 14.3 in 1937. The days of incapacity for labor in each case of sickness has, however, decreased from 27.6 in 1935 to 26.9 in 1936 and 26.5 in 1937. The expenditure per insured has risen fairly steadily from 101.84 marks (\$40.75) in 1934 to 112.34 marks (\$45) in 1937. The largest increase has been in the cost of hospital care and cash benefits, as little more has been expended for medical care by insurance physicians. A suggested explanation of the increased illness and consequent additional costs is that employees added in recent years have been unfamiliar with the risks of mining.

The average age of members has steadily increased from 32 years and 11 months in 1927 to 35 years and 8 months in 1937. At the present time the average days of incapacity due to illness annually increases steadily with the age of the employee.

RADIOLOGISTS AND THE WAGNER BILL

Radiologists are especially interested in the feature of the Wagner bill which proposes the "construction of 500 diagnostic centers 'as an initial development' at a cost of \$30,000 each. These would not only assist the state cancer hospital in cancer diagnosis and treatment but would also serve 'for diagnosis and therapy which would be beyond the resources that the local physicians of the neighborhood normally would have for equipment in their offices.' Thus provisions are made for about ten centers in each state to serve, presumably without charge and regardless of ability to pay, all citizens whose attending physician desires radiological or pathological procedures in diagnosis."

Mr. Mac F. Cahal, executive secretary of the Inter-Society Committee for Radiology, in the Special Bulletin from which the foregoing statements were quoted, further says:

Is there any evidence whatever to justify the construction of 500 free diagnostic centers to duplicate existing facilities? There is no way of knowing the exact number of roentgen installations in this country today. We do know, however, that there are more than 2,000 radiological specialists equipped and trained to give diagnostic consultation. We do know that there are more than 6,000 hospitals having roentgen departments. And we do know that 98.5 per cent of the people residing within the United States live within 30 miles of a hospital.

If the Wagner bill becomes a law it will inevitably supplant competent private practitioners with salaried political appointees. Does the record of the federal state offer any indication that this system would result in anything but inferior service to the sick, rich and poor? Although the bill does not provide for compulsory health insurance, it opens, by means of governmental subsidies and consequent government control, an even more direct road to state medicine than would compulsory insurance.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Infantile Paralysis Center for Negroes.—The National Foundation for Infantile Paralysis has granted \$161,350 to establish a center for infantile paralysis at Tuskegee Institute, Tuskegee. Of the total, \$81,400 will be for construction, \$39,950 for equipment and \$40,000 for one year's maintenance for the thirty-six beds which the plans provide. Construction will begin without delay, it was announced. It is hoped that the center will provide modern treatment for Negro infantile paralysis victims and serve as a training unit for Negro physicians, nurses and physical therapists. The fifteen bed John A. Anderson Hospital, affiliated with the institute, will be available for use by the center. The institute also plans an educational program in the care and treatment of poliomyelitis. Dr. John W. Chenault, director of orthopedic surgery at Tuskegee, will be in charge of the new center.

ARKANSAS

County Society Sponsors Educational Publicity.—The Johnson County Medical Society is the first county society in the state to introduce a publicity campaign in the county papers, using the prepared weekly advertisements on organized medicine and medical topics which have been favorably commented on in other sections, according to the state medical journal. This material will appear weekly throughout the coming year. The first advertisement, which appeared June 8, was entitled "Is Your Doctor an M.D.?" and stressed the importance of distinguishing between the doctor of medicine and the faddists and cultists who usurp the title of doctor.

CALIFORNIA

Changes in Health Officers.—Dr. Francis H. Gambell, Willows, has been appointed health officer of Glenn County succeeding Dr. Frank M. Lavson. Dr. Cornelius W. Lane, Crescent City, has been named to succeed Dr. Wilson Stegeman as health officer of Del Norte County. Dr. Frank I. O'Neill, Oroville, has resigned as health officer of Butte County.

Fined for False Therapeutic Claims.—W. S. Yeomans was found guilty of false and fraudulent therapeutic claims recently by Judge E. P. Woods, Montebello Township Court, and fined \$50. Yeomans, who claimed on the witness stand that he could cure toothaches and grow fingernails and cure cancer and tuberculosis, it was stated, was ordered to cease selling his medicine as a cure for any disease. The medicine was said to be a weak solution of lime water with no curative value.

ILLINOIS

Society News.—At a meeting of the Perry County Medical Society near Pinckneyville June 1 Drs. Oliver Abel Jr. and John W. Thompson, both of St. Louis, discussed arthritis and surgical conditions of the abdomen, respectively. Dr. Thompson also addressed the Jefferson-Hamilton County Medical Society in West Frankfort June 21 and Dr. Andy Hall Jr., St. Louis, spoke on "Transurethral Prostatic Resection."—The McDonough County Medical Society was addressed at Macomb May 25 by Drs. Paul H. Harmon, Springfield, and Samuel Perry Rogers, Chicago, on "Treatment of Acute and Chronic Osteomyelitis" and "Injuries to Muscles and Tendons" respectively.

Chicago

Special Society Elections.—Dr. Harold K. Gibson was chosen president-elect of the Chicago Gynecological Society at its annual meeting June 16; Dr. Julius E. Lackner was installed as president. Other officers include Drs. Charles E. Galloway, Evanston, vice president; Edward D. Allen, secretary, and George H. Gardner, treasurer.—At the annual meeting of the Chicago Society of Internal Medicine recently Dr. James G. Carr was elected president; Dr. Leroy H. Sloan, vice president, and Dr. Clarence F. G. Brown, secretary-treasurer.—Dr. Gerard N. Krost was recently elected president of the Chicago Pediatric Society and Dr. George F. Munns, Winnetka, reelected secretary.

Executive Dean Named for University of Illinois.—Dr. Raymond B. Allen, dean of Wayne University College of Medicine, Detroit, has been appointed executive dean of the Chicago colleges of the University of Illinois, effective September 1. This position has been created to coordinate the educational and research activities of the university's medical, dental and pharmacy units. The three colleges in Chicago will continue as separate entities, however. In the new executive position Dr. Allen will be a direct representative of President Arthur Cutts Willard, whose office is on the main campus at Urbana. Dr. Allen graduated at the University of Minnesota Medical School, Minneapolis, in 1928. He served as teaching fellow in anatomy at his alma mater from 1924 to 1927 and assistant surgeon at the Northwest Clinic at Minot, N. D., from 1928 to 1930. He was associate dean in charge of graduate study at Columbia University College of Physicians and Surgeons, New York, from 1934 to 1936, when he was appointed dean of Wayne University College of Medicine.

INDIANA

New Bone and Joint Club.—Dr. Eugene B. Mumford, Indianapolis, has been elected president of the newly organized Bone and Joint Club of Indiana, which held its first annual meeting at the Indianapolis Athletic Club April 26. Dr. Gordon W. Batman, Indianapolis, was chosen vice president and Dr. Charles F. Thompson, Indianapolis, secretary-treasurer. Dr. August F. Knoefel, Terre Haute, conducted a round table discussion on forearm fractures and after the dinner Dr. Walter H. Baker, South Bend, one on injuries to the shoulder joint.

Tuberculosis Survey.—Chest roentgenograms are being taken of the school children under the jurisdiction of the Madison and Huntingburg district health departments. Dr. Warren Palmer Dearing, assistant surgeon, U. S. Public Health Service, is making the survey, which was undertaken to complete a study as to the cause of abnormal prevalence of tuberculosis in Kentucky and Tennessee. According to the state board of health, the tuberculosis death rate in these two states is very high and shades off into all the surrounding states. It has been brought out that this area of high tuberculosis death rate corresponds accurately with the limestone areas. The study in Indiana is to ascertain whether this abnormal prevalence of tuberculosis in limestone areas occurs in Indiana, since Madison is in the limestone region and Huntingburg is not.

IOWA

Spotted Fever.—Eleven cases of Rocky Mountain spotted fever were reported to the state department of health during the first twenty-nine days of June, bringing the total number of cases thus far this year to sixteen including two deaths (THE JOURNAL, June 24, p. 2613). A first case was recently reported from the following seven counties: Appanoose, Clinton, Hamilton, Polk, Wayne, Webster and Wright; the remaining cases occurred in Adams, Jackson, Muscatine and Wapello counties. Three of the patients were apparently benefited by convalescent spotted fever serum.

Society News.—Dr. Julian M. Bruner, Des Moines, addressed the Jasper County Medical Society in Newton May 2 on "The Ligation Treatment of Varicose Veins."—At a meeting of the Lee County Medical Society May 10 in Fort Madison the speakers were Drs. Vernon W. Petersen, Iowa City, on "Surgical Treatment of the Lungs and Pleura"; Alto E. Feller, "Diagnosis and Treatment of Hay Fever and Asthma," and George B. Crow, Burlington, "Heart Disease."—The Woodbury County Medical Society was addressed in Sioux City May 23 by Dr. Ralph H. Luikart, Omaha, on "Indications for Interference During Labor and the Technic."

LOUISIANA

Dr. Lorio, President of State Medical Society, Indicted.—Dr. Clarence A. Lorio, state senator, president of the Louisiana State Medical Society, physician at Louisiana State University, Baton Rouge, and, according to the New York Times, political boss of East Baton Rouge Parish, was indicted by the grand jury in Baton Rouge July 14 for embezzlement. In one indictment against Dr. Lorio it was reported that university material worth \$240 was involved. Dr. Lorio was indicted separately also for "receiving and having embezzled goods" in his possession. The grand jury which has been investigating charges of graft at Louisiana State University since the resignation as president of James Monroe Smith, Ph.D., and his flight to Canada, according to the

Times, brought in twenty-eight true bills, twenty-three of which were against Dr. Smith and two against Dr. Lorio, who was said to be a close friend of the late Senator Huey P. Long and who was one of the attending physicians with him when he died. Dr. Lorio was released under \$12,500 bond. The *Times* for July 15 reported that Dr. Lorio had been suspended as university physician. Dr. Paul T. Talbot, New Orleans, secretary of the Louisiana State Medical Society, announced that Dr. Lorio had resigned as president of the society. Dr. Lorio graduated at Tulane University of Louisiana School of Medicine in 1918. He served in the U. S. Navy during the World War, coming to Baton Rouge in 1919. He is chief surgeon for the Louisiana State Penitentiary Hospital and a member of the staff of the East Louisiana Hospital for the Insane, Jackson. He is also a member of the advisory council of Louisiana University Medical Center, New Orleans. He served as president of the East Baton Rouge Parish Medical Society in 1928 and later as councilor for the Sixth District Medical Society. It was stated that Dr. Lorio had been receiving more than \$10,000 a year as a member of the staffs of the state institutions.

MAINE

Session on Obstetrics and Gynecology.—The New England Obstetrical and Gynecological Society held its spring meeting in Portland May 24. The speakers included Drs. Theodore M. Stevens on "Congenital Deformity"; Ralph L. Reynolds, Waterville, postpartum care; Walter F. W. Hay, "Endometriosis of Vagina"; Carl E. Dunham, "Metastatic Carcinoma of Ovaries, Three Months Postpartum," and Adam P. Leighton, "It Has Happened Here."

MASSACHUSETTS

New Committee on Industrial Health.—The Massachusetts Medical Society recently appointed a committee on industrial health composed of Drs. William Irving Clark, Worcester, chairman; Louis R. Daniels, Watertown, and Noel G. Monroe, Boston.

Society News.—Prof. August Krogh, University of Copenhagen, lectured at Harvard Medical School, Boston, May 11 on "The Regulation of the Circulation in Man as Illustrated by Experiments on Change of Posture."—A symposium on short wave therapy was presented before the New England Society of Physical Medicine May 24 by Drs. Michel Pijoan, Herman A. Osgood, Heinrich G. Brugsch and William D. McFee, Boston.

MICHIGAN

Personal.—Dr. Thomas R. K. Gruber, superintendent of Eloise Hospital, was reelected president of the Health Council of Metropolitan Detroit, newspapers reported.—Dr. Henry Wellington Yates, formerly president of the Wayne County Medical Society, Detroit, has been appointed a member of the city plan commission of Detroit, succeeding Dr. Francis B. Jarzembowski.

Premarital Medical Examination Act Amended.—Couples planning to be married will have thirty days instead of fifteen in which to complete their medical examination requirements before applying for a license to marry in accordance with a recent amendment, effective immediately. The new law also corrects a provision of the 1937 act which worked a hardship on certain persons having so-called "Wassermann-fast" cases of syphilis which would not respond to treatment. Under the amended law, marriage is possible for persons who have syphilis in a noncommunicable stage, provided there is no danger to the health of the marital partner or to the issue of such a marriage. Certificates for this special dispensation will be granted by the state commissioner of health on application by the examining physician. These special certificates will not be public records, according to the state health department.

MISSISSIPPI

Society News.—Orren W. Hyman, Ph.D., dean, University of Tennessee School of Medicine, Memphis, addressed the Delta Medical Society in Greenville April 12 on "What the Present Trend Towards Socialized Medicine Is Going to Do to the General Practitioner."—At a meeting of the Coast Counties Medical Society April 5 Dr. William C. Hannon, Mobile, Ala., spoke on "Chronic Osteomyelitis in Children."

Physician Honored at State Meeting.—Dr. Daniel J. Williams, Gulfport, health officer of Harrison County for twenty-five years and formerly president of the Mississippi

State Medical Association, was presented with a silver cup at the recent annual meeting of the association for "outstanding service rendered organized medicine since 1891." Dr. Williams graduated at the Tulane University of Louisiana School of Medicine, New Orleans, in 1890. Recently he was guest of honor at a dinner given by the Gulf Coast Medical Society.

NEBRASKA

Society News.—Dr. Andrew C. Ivy, Chicago, addressed the Omaha-Douglas County Medical Society May 9 on "Review of the Vitamins from the Viewpoint of Therapy"; Dr. John F. Gardiner discussed tuberculosis. Dr. Harold E. Eggers was the speaker May 23 on "Treatment of Carcinoma, Experimental and Clinical Phases."—At a meeting of the Southwestern Nebraska Medical Society in McCook May 25 Omaha physicians presented the following papers: Drs. Herman M. Jahr, "Care of the Newborn"; Lloyd O. Hoffman, "Management of Breech Presentations," and Charles F. Moon, "Normal Delivery or Forceps, Indications and Contraindications."—Dr. Willson B. Moody, Omaha, addressed the Tri-County Medical Society (Dodge, Washington, Burt) at a meeting in Fremont May 29 on coronary disease.—Drs. William Jepson and Ernest A. Jenkinson, Sioux City, Iowa, discussed cancer at a meeting of the Madison Six County Medical Society in Tilden June 20.

NEW JERSEY

Personal.—Dr. Andrew F. McBride, Paterson, celebrated the fiftieth anniversary of his graduation from Columbia University College of Physicians and Surgeons recently. Dr. McBride has been president of the Medical Society of New Jersey, member of the House of Delegates of the American Medical Association and mayor of Paterson. He has also served as state commissioner of labor and has numerous civic and fraternal affiliations.—Dr. Charles Henry Schlichter, Elizabeth, was recently honored at a testimonial dinner in celebration of his sixty-fifth birthday by his colleagues on the staff of the Elizabeth General Hospital. Dr. Schlichter was made a member of the senior staff of the hospital.

NEW YORK

New Head of Grasslands Hospital.—Dr. Edwin L. Harmon, for the past nine years assistant director of the University Hospitals, Cleveland, has been appointed medical director of Grasslands Hospital, Valhalla. He succeeds Dr. Frederick C. Smith, who has been acting director since the resignation of Dr. Claude W. Munger in 1937. Dr. Harmon graduated from Western Reserve University School of Medicine in 1927. He will take charge at Grasslands August 1.

Society News.—Dr. Zacharias Bercovitz, New York, addressed the Utica Academy of Medicine May 18 on "Diagnosis and Treatment of Chronic Ulcerative Colitis."—Dr. Winfield W. Scott, Rochester, addressed the Oswego County Medical Society, Oswego, May 24, on diseases of the prostate, with emphasis on points of interest to the general practitioner.—Dr. Eugene F. Traub, New York, addressed the Putnam County Medical Society in May on "Parasitic Skin Diseases."—Dr. Joseph B. Loder, Rochester, spoke on "Complications of an Emergency Nature in the Practice of Obstetrics" at a meeting of the Niagara County Medical Society May 9 at Lockport.

New York City

Food Poisoning Affects 500 Children.—An outbreak of food poisoning that affected 500 school children of Staten Island was reported June 25 and 26 in the *New York Times*. The source of the outbreak was not definitely determined, but it was suspected that egg salad sandwiches served in the children's lunches might have been the cause. The lunches were prepared in a kitchen at one of the public schools on the island by a group of WPA workers as part of a child nutrition project among children whose parents are on relief rolls. About 400 children were attended in hospitals and the illness was mild, it was said. Several adults who ate some of the sandwiches also became ill.

Central and Neurological Hospital Closed.—The Central and Neurological Hospital on Welfare Island, which has a capacity of 470 beds, ceased to function July 6, when the new Welfare Hospital for Chronic Diseases took over its patients. Most of the old buildings will be demolished, the department of hospitals announces; one or two may be retained to relieve overcrowding in the New York City Cancer Institute. The old

hospital was opened in 1909 with a capacity of 150 beds as an infirmary for the Home for Dependents. It was subsequently enlarged and in 1912 became known by its present name. It has been enlarged and improved from time to time by the addition of x-ray and radiographic units, an occupational therapy annex and reconstruction of the operating room unit.

Personal.—Dr. Philip R. Lehrman has been promoted to be clinical professor of neurology and psychiatry at Columbia University College of Physicians and Surgeons.—Dr. Sigismund S. Goldwater, commissioner of hospitals, received the honorary degree of doctor of public health at the commencement of Cornell University June 7.—Dr. Victor G. Heiser received the honorary degree of doctor of humane letters from Temple University, Philadelphia, at the commencement June 15.—Christian Carl Carstens, Ph.D., executive director of the Child Welfare League of America since 1921, died in New York Hospital July 4 of coronary thrombosis, aged 74. Mr. Carstens was chairman of the section on handicapped children at the White House Conference on Child Health and Protection in 1930.

Welfare Agencies Merge.—The Association for Improving the Condition of the Poor and the Charity Organization Society recently combined as a single agency with the name Community Service Society of New York. Mr. Barklie Henry, president of the first named agency, is president of the new society and Mr. Walter S. Gifford, president of the Charity Organization Society, became chairman of the board of the combined organization. The two agencies had an endowment of \$28,000,000 and their property was valued at \$1,000,000. Headquarters are at 105 East Twenty-Second Street. Porter R. Lee, director of the New York School of Social Work, an operating division of the Community Service Society, died recently and Walter W. Pettit, a member of the school's staff for many years, has succeeded him. The school was founded in 1898 by the Charity Organization Society.

PENNSYLVANIA

Society News.—Dr. Edwin W. Rodenheiser, Upper Darby, addressed the Delaware County Medical Society, Essington, June 8 on "The Differentiation of Abdominal Conditions in Children."—Dr. John P. Griffith, Pittsburgh, addressed the Fayette County Medical Society, Uniontown, June 8 on acute surgical conditions in the abdomen.

New Hospital Dedicated.—The new building of the Montgomery Hospital, Norristown, a \$600,000 structure with a capacity of 134 beds, was opened and dedicated June 8. Funds for the hospital were raised in a community campaign in 1937. Dr. Frank C. Parker, chairman of the medical board, and Mr. A. T. Eastwick, president of the board of directors, were the speakers at the dedication.

Philadelphia

Society News.—Phyllis Blanchard, Ph.D., and Myrtle B. McGraw, Ph.D., addressed the Philadelphia Pediatric Society May 9 on "Modern Interpretation of Intelligence Tests" and "Scope and Limitations of Studies in Infant Behavior to Pediatric Practice" respectively.—At a meeting of the Pathological Society of Philadelphia May 11 the speakers were Drs. Irving J. Wolman on "Idiopathic Hypertrophy of the Heart in Infants"; John Eiman, Abington, Pa., "Steps in the Development of Arteriosclerosis: Preliminary Report," and Herbert Fox, "Tuberculosis and Its Control in Infrahuman Primates: the Experiences of Thirty-Five Years."

Personal.—An oil portrait of Dr. William A. Steel, professor of principles of surgery, Temple University School of Medicine for many years, was presented to the university recently by the classes of 1938 and 1939.—Dr. Solomon Solis-Cohen received the honorary degree of doctor of science (honoris causa) at the annual commencement of the Philadelphia College of Pharmacy and Science June 7.—Dr. Winifred Bayard Stewart, assistant clinical professor of neurology, Woman's Medical College of Pennsylvania, was recently made clinical professor.—Dr. Lewis C. Scheffey has been appointed clinical professor of gynecology at Jefferson Medical College.

New Director of Wistar Institute.—Edmond J. Farris, Ph.D., associate in anatomy in charge of operations at the Wistar Institute of Anatomy and Biology, has been named executive director. He succeeds Dr. Milton Jay Greenman, who died April 7, 1937. Dr. Farris, who is 32 years old,

taught anatomy at the University of Buffalo and the Medical College of South Carolina before joining the institute staff three years ago, according to a newspaper account. Dr. Esmond R. Long, director of the Henry Phipps Institute, University of Pennsylvania, was elected president of the Wistar Institute; Dr. Alfred Newton Richards, recently chosen to succeed Dr. Alfred Stengel as vice president in charge of medical affairs at the University of Pennsylvania, and William H. DuBarry, assistant to the president of the university, were made members of the board of managers.

TENNESSEE

Regional Meeting.—Dr. Jesse P. Baird, Dyersburg, was elected president of the West Tennessee Medical and Surgical Association at its forty-eighth annual meeting in Huntingdon May 25. Among the speakers were Drs. Samuel T. Parker, Jackson, on "Conservative Treatment of Sinus Diseases"; John Jackson, Dyer, "Home Treatment of Pulmonary Tuberculosis"; James S. Speed, Memphis, "Open Reduction and Internal Fixation of Selected Fracture Cases," and John Owsley Manier, Nashville, "Sulfapyridine in Pneumonia."

Graduate Course at Meharry College.—The second annual graduate course for physicians was held at Meharry Medical College, Nashville, June 5-17. Lectures, clinics and demonstrations were conducted by the staff during the day and at several evening sessions. The following, all of Nashville, were guest speakers at some of the evening sessions:

Dr. Waller S. Leathers, dean, Vanderbilt University School of Medicine.
Dr. Hugh J. Morgan, professor of medicine at Vanderbilt.
Dr. William R. Cate, associate professor of clinical medicine, Vanderbilt.
Dr. John B. Youmans, associate professor of medicine and director of postgraduate instruction, Vanderbilt.
Dr. Sol L. Lowenstein, assistant in clinical pediatrics, Vanderbilt.
Walter B. McFall, D.D.S., vice president, Southern Dental Association.

At the college commencement June 1 John Ellis Turner, LL.D., president of the Lewiston State Normal School, Lewiston, Idaho, was the speaker, on "What the Community Expects of the Medical Profession." Dr. Turner is the father of Dr. Edward L. Turner, president of the college. Dr. John W. Anderson, Dallas, Texas, a graduate of the class of 1885, was the speaker for an alumni and class night program May 31. There were thirty graduates in medicine. James Robert Gladden won the Charles Nelson Medal for scholarship.

TEXAS

Special Society Elections.—The Texas Allergy Association was organized during the recent annual meeting of the State Medical Association of Texas in San Antonio with Dr. James Harvey Black, Dallas, as president and Dr. Boen Swinny, San Antonio, secretary. At the annual meeting of the Texas Railway and Traumatic Surgical Association Dr. George V. Brindley, Temple, was elected president. Dr. Talbot A. Tumbleson, Beaumont, was elected president of the Texas Pediatric Society. Dr. Charles W. Castner, Austin, was made president of the Texas Neurological Society and Dr. Wilmer L. Allison, Fort Worth, was reelected secretary. The Texas Dermatological Society elected Dr. Leslie M. Smith, El Paso, president, and reelected Dr. Duncan O. Poth, San Antonio, secretary. Dr. Curtice Rosser, Dallas, was elected president of the Texas Society of Gastro-Enterologists and Proctologists.

VIRGINIA

Grants for Research.—The John and Mary R. Markle Foundation, New York, has made a grant of \$3,000 to the Medical College of Virginia, Richmond, for research in biochemistry under the direction of J. C. Forbes, Ph.D., associate professor of biochemistry. The Dazian Foundation also made a grant of \$700 for research in preventive medicine.

Dean Appointed at University.—Harvey E. Jordan, Ph.D., professor of histology and embryology and assistant dean of the department of medicine, University of Virginia, Charlottesville, has been appointed dean to succeed the late Dr. James Carroll Flippin. Dr. Jordan, a native of Pennsylvania, graduated from Lehigh University in 1903 and took his doctorate at Princeton in 1907. He went to the University of Virginia as adjunct professor of anatomy in 1907, became associate professor in 1908 and professor of histology and embryology in 1911. He has been assistant dean since 1928.

WASHINGTON

Society News.—Drs. Frank R. Maddison and Carroll C. Carlson addressed the Pierce County Medical Society, Tacoma, recently on "The Normal and Pathologic Physiology of the Biliary Tract" and "Objectives and Methods of Psychotherapy in Patients Without Psychosis" respectively.—Dr. Warren C. Hunter, Portland, Ore., addressed the Cowlitz County Medical Society in Longview recently on "Thrombosis and Pulmonary Emboli."—Drs. Laurence Selling and Alfred Gurney Kimberley, Portland, Ore., addressed a recent meeting of the Walla Walla Valley Medical Society in Walla Walla on herniation of the nucleus pulposus and hypertrophy of the ligamentum flavum and other causes of low back pain.

GENERAL

Women's Clubs Sponsor Home Safety Program.—The General Federation of Women's Clubs is beginning a home safety program to reduce the number of deaths and injuries caused by fires and accidents in homes. A home safety division has been organized by Dr. Josephine L. Peirce, Lima, Ohio, who is chairman of the federation's department of the American home. Mrs. Chester E. Edwards, Grand Rapids, Mich., is chairman of the new division. Two separate programs, one on fire protection and the other on the prevention of falls and other home accidents, will be offered to the 14,500 member clubs in the federation.

Examining Board to Close Founders' Group.—At the annual meeting of the American Board of Surgery held recently in New York, it was decided that the founders' group will be open to eligible candidates until Jan. 1, 1940. In order to be eligible, candidates must have limited their work strictly to surgery for at least fifteen years prior to Jan. 1, 1937, the date of the board's organization. The office of the secretary, Dr. John Stewart Rodman, 225 South Fifteenth Street, Philadelphia, will forward necessary information on request. Any candidate now desiring qualification in the founders' group must make application prior to January 1.

Special Society Elections.—Dr. Martin S. Kleckner, Allentown, Pa., was elected president of the American Proctologic Society at the annual meeting in Brooklyn, June 25-28. Dr. A. W. Martin Marino, Brooklyn, was made vice president and Dr. Curtice Rosser, Dallas, Texas, reelected secretary.—Dr. Frank C. Knowles, Philadelphia, was elected president of the American Dermatological Association at the annual meeting in Montebello, Que., May 31-June 3. Dr. Frederick D. Weidman, Philadelphia, is secretary. The next meeting will be in 1941.—Dr. William W. Hutchinson, Los Angeles, was named president-elect of the Associated Anesthetists of the United States and Canada at the recent annual meeting in St. Louis. Dr. Hugh A. Cunningham, Milwaukee, was made president-elect of the Mid-Western Association of Anesthetists and Dr. Richard Douglas Sanders, Louisville, Ky., of the Southern Association of Anesthetists.

Advisory Council on Medical Education Organized.—Announcement is made of the formation of the Advisory Council on Medical Education at a meeting in Chicago June 24. The purpose of the new council was stated to be: "to correlate the efforts of the universities, medical schools, hospitals, licensing bodies, public health associations and boards of specialists." The organizations represented at the meeting were: Association of American Medical Colleges, American Hospital Association, Catholic Hospital Association, Federation of State Medical Boards of the United States, Advisory Board for Medical Specialties, National Board of Medical Examiners, American College of Physicians, American College of Surgeons, Association of American Universities, American Association for the Advancement of Science (Division of Medical Sciences) and the American Public Health Association. The American Protestant Hospital Association and the Association of American Colleges were elected to membership. Dr. Willard C. Rappleye, dean, Columbia University College of Physicians and Surgeons, New York, was elected president; Dr. Maurice H. Rees, dean, University of Colorado School of Medicine, Denver, vice president, and Dr. Robin C. Buerki, Chicago, director of study of the Commission on Graduate Medical Education, secretary-treasurer. The executive committee consists of the officers and the following: Drs. Anton J. Carlson, Chicago; Harold L. Rypins, Albany, N. Y.; Hugh J. Morgan, Nashville, Tenn., and Arthur W. Allen, Boston.

Changes in Status of Licensure.—The Alabama State Board of Medical Examiners reports the following action:

Dr. Abijah Clements Fields, Birmingham, license revoked Dec. 23, 1938, because of habitual drunkenness.

The California State Board of Medical Examiners reports the following licenses restored at its meeting in February:

Dr. Mahlon C. Cooley, Los Angeles.
Dr. Antonio Lopez de Castillo, Los Angeles.
Dr. William B. Humphrey, Los Angeles.
Dr. Paul F. Eid, San Francisco.
Dr. Louis Kameny, Oakland.
Dr. Samuel C. Long, Bakersfield.
Dr. William R. McDannell, Los Angeles.
Dr. Guy O. McKechnan, Los Angeles.
Dr. William F. Meyer, San Diego.
Dr. Alfred H. St. John, Los Angeles.
Dr. Arthur M. Tweedie, Los Angeles.

At the same meeting the board imposed the following penalties:

Dr. Boyajian B. Armen, Fresno, license revoked, based on narcotic conviction.

Dr. Winfield L. Bartow, placed on probation for five years, having been found guilty of using a fictitious name.

Dr. Arthur Bowen, Los Angeles, placed on probation for three years without narcotic privileges or possession, having been found guilty of prescribing for a known addict.

Dr. Harry W. Boyd, Los Angeles, license revoked for aiding and abetting and use of a fictitious name, both in connection with the so-called Samaritan Treatment for Alcoholism, Los Angeles branch.

Dr. Edward J. Buckley, San Francisco, placed on probation for five years provided that he cease practice from March 1 to July 1, 1939, having been charged with aiding and abetting an unlicensed practitioner, namely William Van Buren.

Dr. Claire W. Fulton, Los Angeles, placed on probation for five years for using a fictitious name.

The Illinois State Department of Registration and Education announces the following:

Dr. Leo Ginsburg, formerly of Chicago, license revoked April 22 for his conviction of violation of the Harrison Narcotic Act.

Dr. Floyd J. Kesling, formerly of Peoria, license revoked April 18 for his conviction of violation of the Harrison Narcotic Act.

The New York State Board of Medical Examiners has recently reported the following action:

Dr. Peter Kleinkopf, New York, license reinstated March 2; it was suspended June 17, 1938.

Dr. William Irving Jablon, formerly of Richmond Hill, N. Y., license revoked Dec. 18, 1938.

Dr. John Vincent Grieco, New York, license suspended January 27 for fraud and deceit in the practice of medicine and for having aided and abetted an illegal practitioner.

CORRECTION

Standardization of Hemoglobinometer.—In an article by Dr. Royall M. Calder entitled "Blood Studies in Brucellosis" in THE JOURNAL, May 13, appears the statement that the Sahli hemometer had been standardized by the National Bureau of Standards. We are informed that this is an error and that the National Bureau has never undertaken the standardization of Sahli instruments. Dr. Calder says, however, "The accuracy of our observations is not involved, since our instruments were standardized by reliable chemists in one of the medical schools according to the method of Van Slyke."

Government Services

Wellcome Prize Awarded

Col. Albert G. Love, U. S. Army Medical Corps, received the Wellcome Prize of the Association of Military Surgeons of the United States at the recent meeting of the association in Washington, D. C., in conjunction with the Tenth International Congress of Military Medicine and Pharmacy. The award of \$500 went to Colonel Love for a paper presented before the congress on "Probable Casualties in War and Methods of Calculation."

Dr. Reichard New Medical Officer at Narcotic Farm

Dr. John D. Reichard, head of the neuropsychiatric service at the U. S. Marine Hospital, Ellis Island, New York, has been appointed medical officer in charge of the U. S. Narcotic Farm at Lexington, Ky. He succeeds Dr. Walter L. Treadway, who has been assigned to the University of California Medical School, San Francisco, to direct a survey of the care of mental patients in the state. Dr. Seymour D. Vestermark, associate staff member in charge of the diagnostic clinic of the field studies in mental hygiene, U. S. Public Health Service, will succeed Dr. Reichard at Ellis Island.

Cancer Research

Speaking at the opening of the new laboratories of the Imperial Cancer Research Fund, Sir Frederick Gowland Hopkins, biochemist, said that progress toward understanding the nature of cancer was increasing remarkably fast. It was most unlikely that a complete mastery of cancer would arrive until a fuller knowledge of its intimate nature as a phenomenon of uncontrolled growth was reached. Morphologic studies had played a considerable part in cancer research. They yielded indispensable information but could throw little light on the underlying phenomenon of morbid growth. In a great number of cases the initial influence of an external agent which might cause normal cells to become cancerous was now recognized. When this had acted for a sufficient time—fortunately it was a very long time—cells might be led to grow pathologically. An example was long contact with certain chemical substances, as in the occupational cancers. Such action was exerted most readily on the skin and superficial parts, where the effect was easy to observe. But it was quite possible that provocative factors, doubtless differing in kind, were concerned elsewhere in the body. We were apt to speak of this action as prolonged "irritation"—a word with vague meanings. We had to learn why only in certain circumstances irritation became a stimulant to growth. If constitutional changes must exist before growth could begin, we should look on them as links in the chain of causation. Did external factors supply only an initial impulse to growth, which, once started, continued without their continued influence? This must be true of such factors as chemical or mechanical irritation and radiation. On the other hand, the continued presence of an agent such as a virus might be necessary for the continuance of growth. We had long known that tar could produce cancer, but we now knew that certain specific substances in it were alone responsible. Interest in these was increased by the fact that they were akin to substances natural to the body, for instance to the sex hormones. How far a virus was a necessary factor in cancer was not settled, but it certainly played a part in the general field of morbid growth. Cancer research was going deeper into the nature of the phenomenon and yielding results of unforeseen promise.

At the first annual meeting of the Faculty of Radiologists (formed by amalgamation of the British Association of Radiologists and the Society of Radiotherapists) the "Cancer Problem" was discussed. Prof. Henry Cohen said that the present treatment of cancer was essentially anatomic. The aim of the surgeon was to excise and radiotherapy was similarly directed against local sites. But therapy in general aimed at restoring disturbed functions to normal and eradicating or nullifying causative factors. Certain observations on the cancer cell, notably its capacity to derive energy from converting dextrose into lactic acid, and occurrence of dextrorotatory amino acids in the products of its protein hydrolysis, seemed to be significant, but no therapeutic measures had been based on them.

Dr. J. R. Paterson said that surgery and radiotherapy were the only effective methods of treating malignant disease. Radiotherapy might be curative or palliative. Only cases diagnosable in the early stage were curable and there were only four curable types, carcinoma of the breast, the mouth and lip, the skin and the uterus. The first was best dealt with surgically and the other three were best handled at first by radiotherapy, provided it was radical. Though cancer of the larynx and pharynx could not be classed as curable by radiotherapy, cures were exceptionally obtained.

The Law on Abortion

A demand has been made by a section of the medical profession for amendment of the law on abortion. A committee appointed by the government to inquire into the subject has presented its report. It recommends that the law should be so clarified as to make it plain that the induction of abortion is legal when carried out to save the life of the woman or to prevent serious impairment of her health. But it expresses strong opposition on ethical, social and medical grounds to any broad relaxation of the law. The committee would have welcomed the legalization of the termination of pregnancies resulting from rape but has been unable to devise a scheme to meet the difficulties. Apart from this, it does not consider that any nonmedical grounds should be a legal justification for the operation. Subject to reservations by two members, the committee recommends that therapeutic abortion should be compulsorily notifiable by the operator to the health officer. The object is to prevent abuse of the law, if clarified as suggested. The majority of the committee was not in favor of compulsory notification of other abortions, but a minority was in favor of this for statistical and research purposes.

Further control of the sale of drugs reputed to have abortifacient properties is recommended. Legislation should be introduced to suppress the advertisement of "female pills" and similar preparations. The majority of the committee would not recommend that the public health services should be used for the unrestricted dissemination of birth control advice but felt that more should be done to give contraceptive advice to married women whose health would be adversely affected by pregnancy and that this should not be limited by too narrow an interpretation of medical grounds. Two members held that advice should be given on economic grounds. It is estimated that the annual number of abortions in England and Wales is between 110,000 and 150,000, of which perhaps 40 per cent are criminal.

Restriction of Admission of Alien Physicians Into Australia

The General Medical Council of the United Kingdom has protested to the Victorian Medical Board and to Melbourne University against Victoria's refusal to register alien physicians who, after passing a short university course in the United Kingdom, are registered but not permitted to reside in the United Kingdom and who then seek registration in Victoria, under their qualification in the United Kingdom. The council points out that the effect of amending the Victoria medical act passed last December is materially to restrict the privileges extended to United Kingdom physicians. The present method of registration in the United Kingdom is designed not to make it easier for foreign graduates to obtain registrable qualifications but to curtail their rights to be freely admitted. Their number is restricted to seven each year. The council's power to recognize medical diplomas granted in Victoria depends on the maintenance by Victoria of the privilege granted to physicians registered in the United Kingdom to practice in Victoria. The Victorian Medical Board and the university are considering the situation. The abolition of reciprocity would handicap Victorian physicians who wish to go to the United Kingdom for postgraduate study. About eighty go each year, and if reciprocity should be withdrawn they could not practice or take up an appointment while in England. The Victorian amending act that has been referred to allowed only those physicians to register who had studied at least five years in Victoria or in a country recognizing Victorian qualifications. All foreigners except those from Italy, with which Victoria has established reciprocity, are excluded unless their countries reciprocate. Similar legislation is already in force in Western Australia and Tasmania.

The Making of Medical Men

Delivering the Bancroft oration in Brisbane last week, on the subject "The Making of Medical Men," Sir Alan Newton, F.R.C.S. (England), vice president and censor in chief of the Royal Australian College of Surgeons and senior surgeon at the Royal Melbourne Hospital, expressed some criticism of our system of medical education. The needs of the general practitioner, he said, were paramount in medical education and the university course in medicine should be designed primarily to fit students for general practice. Over the past ten to fifteen years there has been a tendency to overcrowd the curriculum, and the faculty of medicine in most universities had become unwieldy. To remedy this he proposed that first year subjects be delegated to schools and taught with English and history to form a cultural background; that biology should also be taught in schools, with greater importance attached to biologic principles than to structural detail; that botany be eliminated, as pharmaceutical preparations are now largely standardized preparations and the original material rarely used; that psychology, radiologic diagnosis and pharmacology might also be omitted (the last being merged into therapeutics); that lectures on anesthesia be replaced by demonstrations, and that instruction in the physiology of the special senses be reduced. He suggested that a study of the minute anatomy of the nervous system was unnecessary and that emphasis should be laid on a knowledge of the anatomic relations of structures. Special subjects should then be taught as postgraduate instruction.

The general practitioner required a thorough knowledge of general pathology but only a limited scope of special pathology: he need not be a biochemist, he need not be an x-ray specialist; but obstetrics was most important for him. There was a deep need for a medicosocial clinic and provision for every student to visit the homes of patients in order that he might understand something of their environment and its relation to their physical condition. Furthermore, wise general practitioners were needed to teach the art as well as the science of medicine. Sir Alan suggested as an expedient the elimination of the unfit after the first year's work at the university. In this way some control could be exercised over the number and the intellectual standard of those entering the medical profession.

Refugee Doctors for Rural Areas

There is under consideration in several Australian states legislation proposing a system of regional registration for refugee doctors who have the necessary qualifications for general practice in an Australian community. This regional registration will permit a foreigner to practice only in a specified area. It is proposed that certificates be issued for twelve months, subject to renewal at the end of that time. After five years of regional practice a foreign doctor would be entitled to seek registration among the general body of medical practitioners in the state.

In all Australian states, refugee doctors, even though their qualification and experience are beyond all reasonable doubt, are debarred from immediate registration as medical practitioners. Beyond making doubly sure that a foreign doctor is fitted to practice his profession in Australia, these restrictions are designed to protect those already in practice from undesirable competition and also to safeguard the prospects of those younger men and women who are now qualifying for the practice of medicine. At the same time it is undesirable that Australia should reject the medical knowledge, skill and experience that are being brought into this country by some refugees from Europe. A compromise would be achieved if refugee doctors were given opportunities to practice in country districts where medical service is now lacking. There is, however,

another aspect to the question, in that if the difficulty of obtaining medical practitioners for country areas is caused not so much by an actual shortage of doctors as by inadequate remuneration and other considerations for medical services required in country hospital districts, then such appointments are as little likely to attract refugee doctors as Australian doctors.

The attitude of the British Medical Association toward the scheme is definite—that the proposed subsidy of £500 per annum is quite insufficient for any practitioner, whether of foreign or of British training, and that it should be increased to £1,000. If this should be done, the branch feels confident that there would be a good supply of British practitioners for the districts in question. Should no local graduates be available for the subsidized areas at such a salary, the branch has no objection to foreign graduates filling the positions temporarily. However, the number of medical students close to graduation in Australia is greater now than it has been for some years, and it is therefore becoming increasingly difficult for local graduates to be absorbed in remunerative practice.

BERLIN

(From Our Regular Correspondent)

June 8, 1939.

The New Bureau of Hygiene in Munich

According to legal regulations, only the state may establish bureaus of hygiene, but the city of Munich was granted permission to build a municipal bureau of hygiene. Munich has distinguished itself as an abode of municipal hygiene since the days of its great hygienist Pettenkofer, and this circumstance favored this special permission. Hygiene work formerly performed by the state has been handed over to the city of Munich. The bureau of hygiene has been established in a building that used to be a trade union building before the national socialist seizure of power. The charitable organizations and societies dedicated to tuberculosis and so on have dissolved their organizations and transferred their equipment to the new bureau of hygiene. The bureau is entrusted with setting up a card index system for the total population of Munich, on the basis of racial and inherited biologic characteristics. An x-ray card index system is provided for special vocations. Thirty-nine stations for advising mothers have been distributed over the city, equipped with thirty-four specialists; these posts examined 62,000 children in 1938. A mother's milk collecting station, furnished with the latest precautionary devices, provides 7 hectoliters of milk monthly for suckling babies having no inherited ailments, whose mothers cannot feed them as required. The personnel of this bureau, which consisted of eight persons in 1933, consists of 249 persons at present; this number includes of course numerous posts that formerly functioned independently.

Syphilis and the Issuing of Marriage Licenses

Dr. Spiethoff, professor of dermatology and syphilology at the University of Leipzig and president of the German anti-syphilis society, expressed himself recently with regard to his specialty. The commentary to the German antisiphilic law reads: "Acquired syphilis generally is not considered infectious any longer, if four years has elapsed since the infection and if for two years at least after sufficiently intense treatment no symptoms have appeared. On the basis of scientific experience a shorter time may be set." Spiethoff's point of view is that a hindrance to a marriage is to be assumed only if the probability of transmission is so great that the danger of infection outweighs the fundamental desire for many and early marriages and every other social consideration. The value of the periods of time mentioned (four and two years) is to be computed differently. The lapse of a two year period of observation that shows no infection after the completion of a sufficiently intense

treatment is sufficient to negate the danger of infection. Accordingly, it is not necessary that four years should intervene from the time of infection. Two years of observation based on satisfactory treatment and with no negative symptoms always eliminates the fear of further infection. On the other hand, during the lapse of a four year period since the infection, defects in the results of the treatment (positive reaction, but with no clinically persisting symptoms) and defects in the treatment itself can be corrected. This correction without limitation applies only to the infection resulting from sexual intercourse, not to danger of infection through the offspring; that is, it has full application only to men, not to women. Even after ten, fifteen or more years after infection a pregnant woman who is syphilitic can infect her child. A treatment that is not thoroughly carried out does not protect the children against syphilis. Only a sufficiently intense treatment of the mother offers a real protection against congenital syphilis. However, if this treatment is defective, a four year period of time cannot correct it.

Streptococci

A recent session of the Medizinische Gesellschaft of Berlin was devoted to a discussion on streptococci. Pesch spoke on the variability and pathogenic significance of streptococci. The main difficulty in the way of investigation is caused by the variability of these bacteria. A classification on the basis of length of chains or microchemical behavior cannot be maintained on account of the change of these properties on different nutrient mediums. The best division still is the one based on behavior on blood agar; thus (1) hemolytic, (2) green-producing, (3) streptococci which do not change blood agar, (4) anaerobic streptococci and (5) enterococci. Serologically and on the basis of antigen analyses, American investigators found twenty-seven different types of streptococci. It is possible to separate human and animal pathogenic streptococci by means of the fibrinolysis test, a good standard for measuring the efficacy of streptococcus serums. Three of the toxins formed by streptococci are definitely known at present: hemolysin, an organotrope necrotizing toxin, and the Dick toxin of scarlet fever. It has been found possible to transform green-producing into hemolytic streptococci in dental granulomas by means of short wave treatment.

Professor Bessau, pediatrician, discussed next the significance of streptococci in pediatrics. Streptococcal sepsis in the newborn and prematurely born is especially dangerous. The contents of pemphigus bullae in the newborn contain nearly pure cultures of streptococci. The frequent occurrence of erysipelas of the newborn is caused mostly by streptococcal sore throat of the nursing persons. Scarlatina is a streptococcal disease. The gate of entrance is always the sore throat except in wound scarlatina. The exanthem is caused by the Dick toxin. Antitoxic serum does not protect prophylactically from scarlatina. It influences septic scarlatina only in large quantities and only in case it was obtained from human beings. Bessau pointed out furthermore that nephrosis in children is probably a pneumo-streptococcal disease, especially since the children die of sepsis or pneumococcal or streptococcal peritonitis mostly.

Professor Lerche spoke on the transmissibility of animal streptococci to man. He explained that in America numerous attacks of epidemic sore throat occurred from Streptococcus epidemicus seu pyogenes, attacks causally connected with the drinking of milk; according to more recent investigations, the scarlatina streptococcus is involved mostly; the organisms are carried as a rule by diseased milkers to the udder of the cow and the admixing to milk occurs from there. In case streptococci are artificially added to milk, they increase their numbers only with difficulty. In Germany no attacks of epidemic sore throat caused by cows with mastitis have been observed, although they have been in America, England, Norway, Sweden and Denmark. At any rate, no persons having

sore throat should be employed in dairies or in stables where dairy animals are kept. Professor Wainemacher spoke finally about streptococcal infections of the teeth. He emphasized the importance of prophylactic measures to avoid infection of the pulp.

Austrian Physicians on Postage Stamps

Shortly before Austria was absorbed by Germany, the postal authorities had the happy idea of commemorating well known Austrian physicians in a series of postage stamps. In general only a few physicians received this honor. The series of Austrian physicians was issued during 1937 and was designated as the "welfare series." These postage stamps give among others a picture of Gerhard van Swieten (1700-1772), who as personal physician of the empress Maria Theresa introduced in Vienna for the training of young physicians instruction at the bedside in place of the study of books. Another stamp had Leopold van Auenbrugger (1722-1809), to whom science is indebted for a knowledge of percussion. His discovery was forgotten, however, and was later again "discovered" by Skoda. The next one shows Karl von Rokitansky, the founder of modern pathologic anatomy (1804-1878), whose five volume textbook of anatomy became the foundation of scientific investigation in medicine. Then there is Joseph Skoda (1805-1887), the originator of physical methods of examination. In addition to percussion, introduced by Auenbrugger, he introduced auscultation. The next postage stamp is dedicated to Ferdinand von Hebra (1816-1880), who gained worldwide renown as a reformer of dermatology. The ophthalmologist Ferdinand von Arlt (1812-1887), who did so much for surgery and diagnosis of the eye, has likewise been commemorated; then there was a postage stamp showing Joseph Hyrtl, the universal anatomist (1810-1894), whose school in Vienna did pioneering service for all Europe. Then there followed a stamp with Theodor Billroth (1829-1894), founder of modern war surgery and originator of extirpation of the larynx and the stomach. The series closed with Theodor Meynert (1833-1892), psychiatrist and anatomist of the brain, whose researches are still recognized. He founded a modern institution for the insane in Vienna and attracted many students, who propagated his idea throughout the world.

The German Society for Microbiology

A short time ago the eighteenth meeting of the German Society for Microbiology was held in Vienna. Professor Prigge of Frankfurt gave the first lecture, on "Bacteriology, Immunology and Epidemiology of Bacillary Dysentery." He demonstrated that the Shiga-Kruse bacilli contain, in addition to the well known toxin, also an endotoxin, which in contradistinction to the first is thermostable and has no protein-like characteristics. Many other types of dysentery bacilli contain only endotoxin, which is responsible for the development of intestinal changes. For the active vaccination of human subjects only a mixture of endotoxin, toxin and antitoxin can be used. In an epidemic of 145 cases in Mecklenburg twenty were fatal. In Kruse E dysentery, which is especially dangerous for young children and old persons and which occurs in Germany almost exclusively, it is especially important that the Gruber-Widal test be made; it produces positive results in more than 63 per cent of the cases. Substitute culture mediums were discussed by Hetteche of Munich and Zimmermann of Breslau. As a substitute for agar, silicic acid and polyvinyl alcohol have been recommended, as well as the soluble cellulose ethers. The role of bacteria in the carious destruction of teeth was discussed by Gins of Berlin. In contradistinction to many earlier investigators, he succeeded in demonstrating that under certain conditions the dental substance serves as food for the bacteria. However, in small children these bacteria of dental caries do

not yet occur. Schlossberger of Berlin discussed the foundations of chemotherapy. Prontosil and its derivatives were discussed by Domagh of Elberfeld. These substances are especially effective against streptococci. Now investigations are being carried out to find chemical substances which are active against other infections (gonococci and various types of viruses). Of special interest was a lecture by Schwarz on the conservation of fish. He found that the best method of conservation for such foods consists in "gassing" them with carbon dioxide in a closed container and at low temperatures. This prevents the growth of the bacteria in the fish.

Accident Insurance Against Occupational Diseases

A proclamation of the government of the German reich for 1939 introduces into Austria the extension of the social insurance laws as they are in force in Germany. Now employees who contract an occupational disease are treated as if they had sustained an accident and thus receive the benefits of accident insurance. They receive free medical or hospital care and, in case of permanent injury of their health or of permanent impairment of their working capacity, a compensation or pension (pension for invalids); however, from time to time they have to submit to an examination so that it may be determined whether the impairment persists to the same extent and degree. The disorders recognized as occupational diseases are listed. The list differs greatly from the one heretofore in force in Austria; it is much more extensive and thus signifies great protection for the working classes.

Organization for Research on Cancer

A short time ago a new Association for Research on Cancer was founded in Vienna. It is really nothing else than a combination of the various organizations which have existed in Austria. The extensive preliminary work which the Viennese Society for Control of Cancer accomplished formerly under its president, Prof. Alex Fränkel, and then under Professor Eiselsberg, is being utilized. The purpose of the new foundation is to obtain extensive statistics on neoplastic disease and thus increase the knowledge of the predisposing factors. The new foundation, which takes the place of the dissolved societies, introduces nothing essentially new but is only a more rigid combination and unification of the previously existing organizations.

ITALY

June 20, 1939.

Appointment of Professor

Prof. Pio Bastai, who taught clinical methodology and pathology at the University of Florence, was recently appointed to the chair of clinical medicine at Padua University. Professor Bastai has written important articles on familial splenomegaly with liver cirrhosis, the pathogenesis of Baumgarten's syndrome and the role of heredity in the pathogenesis of sporadic cases of hemolytic anemia and of a hormone deficiency in the development of pernicious anemia, achylic anemia and chlorosis. He also has written on experimental and spontaneous hypersensitivity. From his studies on the nature of tuberculin reactions he early adopted conceptions on a condition of hypersensitivity which is now known as para-allergy. He was one of the first to report the negativity of the tuberculin reactions in malignant lymphogranuloma. He has carried on important work on encephalitis, herpetic infections, brucellosis and problems of functional surgery. He was the first to resort to partial removal of the parathyroids in the treatment of obliterating thromboangiitis. Professor Bastai and his school have engaged in research on the clinical phenomena of old age during the last ten years. He has written more than thirty articles on the subject. The phenomena of old age are interpreted in his book by such original conceptions that a foreign firm made arrangements for the translation of the book into French.

Aid from Medical Syndicates

The National Medical Syndicate was recognized by law in 1937. Representatives of any medical syndicate can be members. The funds are made up by voluntary donations of the members, the profits of publishing a journal and half the amount charged for drawing up medical certificates. The last mentioned item was established in 1938 in about forty Italian provinces and it produced about 500,000 Italian lire (\$25,000) during the year. Help from the treasury was given to 554 physicians with total expenses of 250,000 lire (\$12,500). The figures are still modest because physicians refuse to ask for help unless they are in great need. The board of directors is planning to enlarge the functions in order to help physicians who are in need and to establish scholarships for sons of physicians and eventually to establish old age insurance.

Professor Belfanti Is Dead

Prof. Serafino Belfanti, a senator and head of the Istituto Sieroterapico of Milan, is dead. He wrote articles on tetanus, diphtheria antitoxin, hemolysins, the specificity of antistreptococcus serum, enzymes, the preparation and dosage of insulin and the phosphatases. The Istituto Sieroterapico has been concerned with the preparation of products for medical, veterinary, industrial and agricultural uses; it publishes the journals *Rassegna di bacteriologia e sieroterapia*, *Biochimica e terapia sperimentale*, *Clinica Veterinaria*, *Bollettino dell'Istituto Sieroterapico Milanese* and *Bollettino della Società Internazionale di Microbiologia*.

Marriages

THOMAS WILLIAM MESSERVY JR., Meggett, S. C., to Miss Elizabeth Walker Gilberson of Charleston, June 2.

KARL P. KLASSEN, Columbus, Ohio, to Miss Elvera Ann Hertz of Cleveland Heights, Ohio, May 29.

C. HARLAN JOHNSTON, Des Moines, Iowa, to Miss Margaret Diesner Alexander of Minneapolis, May 13.

CHARLES CLARK KISSINGER, Washington, D. C., to Miss Mary Stribling of Seneca, S. C., June 22.

THOMAS MCKEAN DOWNS, Bryn Mawr, Pa., to Mrs. Catherine Drinker Bowen of Merion, June 30.

PLINIO H. MONTALVAN, New York, to Miss Ruth Gardiner Warren of Washington, D. C., recently.

LEO IGNATIUS DONOVAN, Washington, D. C., to Miss Dorothy Marie Millard of Brooklyn, May 27.

WILLIAM H. DE RAMUS, Selma, Ala., to Miss Eleanor Faye Miller of Jackson, Tenn., June 17.

FRANK A. KEARNEY II, Phoebus, Va., to Miss Frances Elizabeth Tilman of Saltville, June 10.

EMORY L. MAURITZ, Des Moines, to Miss Verna Lisle Byers of Detroit at Davenport, May 1.

BROOKE BAYLOR MALLORY to Miss Virginia Bailey Carter, both of Lexington, Va., June 16.

JAMES PENNOYER III, Maplewood, N. J., to Dr. MIRIAM H. MELLON of Pittsburgh in June.

JOHN FRANKLIN JONAS, Marion, N. C., to Mrs. Marie Smith Griffin of Valdese, May 31.

PAUL MCNEELY DEATON to Miss Evelyn Goode, both of Statesville, N. C., in June.

ELVIN E. KEETON, Paola, Kan., to Miss Cora Belle Kent of Ypsilanti, Mich., July 1.

ROME TURNER DABBS, Verona, Miss., to Miss Menta Taylor of Philadelphia, June 4.

SIMON J. MAYDET, Chicago, to Miss Anne Koopersmith of Mendota, Ill., June 18.

ROWLAND H. MUSICK, Mendota, Ill., to Miss Virginia Quinn of Shirley, June 10.

ALBERICO MASUCCI, Paterson, N. J., to Miss Katherine Lanterman recently.

BEN F. KILGORE to Miss Gertrude Frey, both of Des Moines, Iowa, June 10.

EMILY A. SVOBODA to Mr. Thomas A. Roscoe, both of Chicago, July 8.

Deaths

Charles Howard Goodrich ☉ Brooklyn; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1894; member of the House of Delegates of the American Medical Association, 1932-1935 and 1936-1938; past president of the Medical Society of the State of New York and the Medical Society of the County of Kings; fellow of the American College of Surgeons; attending surgeon to the Methodist Episcopal Hospital and the Brooklyn Orphan Asylum; consulting surgeon to the Trinity Hospital, Brooklyn, and the Brattleboro (Vt.) Memorial Hospital; aged 66; died, May 6, of coronary thrombosis.

Byron Hubbard Jackson ☉ Scranton, Pa.; Baltimore Medical College, 1898; fellow of the American College of Physicians; member of the American Roentgen Ray Society and the American College of Radiology; member and past president of the Radiological Society of North America; formerly director of the Pennsylvania Tuberculosis Society; aged 65; for many years chief radiologist to the Scranton State Hospital and the Hahnemann Hospital; chief radiologist to the West Side Hospital, St. Mary's Hospital and the Moses Taylor Hospital, where he died, May 16.

Charles Addison Elliott ☉ Chicago; Northwestern University Medical School, Chicago, 1898; professor of medicine at his alma mater; vice president of the American Medical Association, 1927-1928; member of the National Board of Medical Examiners; member of the Association of American Physicians; fellow of the American College of Physicians; formerly a member of the medical council of the U. S. Veterans' Bureau; on the staff of the Passavant Hospital; aged 66; died, June 26, of cardiovascular disease.

Julius Weiss ☉ New York; Long Island College Hospital, Brooklyn, 1902; instructor in clinical surgery at the Cornell University Medical College, 1911-1912, and instructor in gynecology at the New York Post-Graduate Medical School and Hospital, 1926-1928; one of the founders and president of the medical board and on the staff of the Bronx Maternity and Woman's Hospital; on the staff of the Lutheran Hospital; formerly on the staff of the Peoples Hospital; aged 63; died, April 11, in St. Luke's Hospital.

Robert Moore Blanchard ☉ Colonel, U. S. Army, retired, Washington, D. C.; Miami Medical College, Cincinnati, 1899; entered the army as assistant surgeon in 1902; served during the World War; rose through the various grades to that of colonel in 1928; was retired Sept. 30, 1938 by operation of law; fellow of the American College of Surgeons; aged 64; died, May 17, in the Walter Reed General Hospital.

Ralph Augustine McDonnell ☉ New Haven, Conn.; Yale University School of Medicine, New Haven, 1892; clinical professor emeritus of dermatology at his alma mater; consulting dermatologist to the New Haven Hospital and the Grace Hospital; past president of the Connecticut State Medical Society, New Haven County Medical Society and the New Haven Medical Society; aged 70; died, May 26.

Paul Thorndike, Boston; Harvard University Medical School, Boston, 1888; clinical professor emeritus of genito-urinary surgery at his alma mater and the graduate school; member of the Massachusetts Medical Society; member and past president of the American Association of Genito-Urinary Surgeons; on the staff of the Boston City Hospital; aged 76; died, May 28, in West Roxbury.

Lloyd Aloysius Masterson, New Orleans; St. Louis University School of Medicine, 1927; member of the Louisiana State Medical Society; director of the bureau of maternity and infant hygiene of the state board of health; formerly director of St. Landry Parish Health Unit; aged 39; was killed in an automobile accident, May 25, near Atlanta, Ga.

Thomas Andrew Vogel ☉ Columbus, Ohio; Georgetown University School of Medicine, Washington, D. C., 1921; formerly assistant professor of obstetrics at Ohio State University College of Medicine; on the staffs of St. Anthony's Hospital, Mount Carmel Hospital and St. Ann's Hospital; aged 45; died suddenly, April 1, of coronary occlusion.

Charles Homer Ewing ☉ Larned, Kan.; University Medical College of Kansas City, Mo., 1902; formerly secretary of the Kansas State Board of Medical Registration and Examination; at one time county coroner, state representative and member of the state board of health; on the staff of the Larned City Hospital; aged 66; died, May 4.

Robert Hyle Sanders, Rock Springs, Wyo.; University of the South Medical Department, Sewanee, Tenn., 1908; member and past president of the Wyoming State Medical Association; state senator, 1933-1937; on the staff of the Wyoming General Hospital; served during the World War; aged 54; died, April 24, of cirrhosis of the liver.

Herbert Bailey Vail ☉ Belleville, N. J.; Columbia University College of Physicians and Surgeons, New York, 1896; formerly school doctor, police surgeon, health officer and president of the local board of health; aged 71; at one time on the staff of St. Barnabas Hospital, Newark, where he died, April 10, of coronary occlusion.

Harry Oscar Delaney, Beloit, Wis.; Rush Medical College, Chicago, 1903; member of the State Medical Society of Wisconsin; formerly health officer and member of the city board of education; on the staff of the Beloit Municipal Hospital; aged 66; died, April 18, of arteriosclerosis, coronary occlusion and chronic nephritis.

Washington J. Meadows, Greensboro, N. C.; Medical College of Alabama, Mobile, 1894; member of the Medical Society of the State of North Carolina; aged 67; on the staffs of the Wesley Long Hospital, Sternberger Hospital and St. Leo's Hospital, where he died, April 21, of hypertension and arteriosclerosis.

Edson Selden Cummings ☉ Portland, Maine; Medical School of Maine, Portland, 1900; member of the New England Roentgen Ray Society and the Radiological Society of North America; served during the World War; on the staff of the Maine Eye and Ear Infirmary; aged 63; died, April 11, of pneumonia.

Albert William Elmer, Davenport, Iowa; University of Pennsylvania Department of Medicine, Philadelphia, 1886; member of the Iowa State Medical Society; fellow of the American College of Surgeons; on the staffs of Mercy and St. Luke's hospitals; aged 81; died, April 6, of cerebral hemorrhage.

Joseph Mark Sowers, Kula, Hawaii; Northwestern University Medical School, Chicago, 1924; member of the Hawaii Territorial Medical Association; served during the World War; on the staff of the Kula Sanitarium; aged 45; died, March 26, in the Para Hospital of malignant hypertension.

Frank Everett Benjamin ☉ Riverhead, N. Y.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1892; past president of the Suffolk County Medical Society; aged 70; died, April 30, of chronic nephritis, pulmonary thrombosis and cerebral thrombosis.

Lewis Marshall Walker, Cambridge, Mass.; Harvard University Medical School, Boston, 1891; member of the Massachusetts Medical Society, American Psychiatric Association and the New England Society of Psychiatry; aged 72; died, April 4, in St. Augustine, Fla., of pneumonia.

Edwin Clarence Button ☉ Great Bend, Kan.; University of Kansas School of Medicine, Kansas City, 1906; past president of the Barton County Medical Society; health officer of Great Bend; formerly county health officer; on the staff of St. Rose Hospital; aged 59; died, April 9.

David Ruslander, Buffalo; University of Buffalo School of Medicine, 1929; member of the American Psychiatric Association; aged 33; on the staff of the Buffalo State Hospital; died, April 29, in the Edward J. Meyer Memorial Hospital of scarlet fever and acute toxic myocarditis.

Samuel Furman Brasington, Camden, S. C.; Kentucky School of Medicine, Louisville, 1897; member of the South Carolina Medical Association; formerly state senator and mayor of Camden; aged 65; on the staff of the Camden Hospital, where he died, April 27, of hemiplegia.

William Rushmer White ☉ Ellicott City, Md.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1900; medical director of the Patapsco Manor Sanitarium; aged 64; died, April 21, in the Johns Hopkins Hospital, Baltimore, of pneumonia and diabetes mellitus.

Boyd Edwin Wilkinson ☉ Paterson, N. J.; Baltimore Medical College, 1905; member of the Radiological Society of North America; served during the World War; on the staff of the Paterson General Hospital; aged 59; died, April 11, of myocarditis and arteriosclerosis.

Dale Dildy, Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1936; member of the Arkansas Medical Society; on the staff of the State Hospital; aged 27; died, April 5, in Nashville of chronic nephritis, cerebral hemorrhage and hypertension.

DEATHS

349

Irving Henry Russotto, New York; University and Bellevue Hospital Medical College, New York, 1916; served during the World War; on the staff of the Veterans Administration Facility; aged 46; died, April 8, in the Lenox Hill Hospital of mesenteric thrombosis.

Harvey Loren Van Pelt Ⓢ Ithaca, N. Y.; Cornell University Medical College, New York, 1902; formerly member of the board of health; aged 61; on the staff of the Memorial Hospital, where he died, April 26, of injuries received when struck by an automobile.

Lawrence Joseph Osborne, New York; Eclectic Medical College of the City of New York, 1896; Dartmouth Medical School, Hanover, N. H., 1897; for many years member of the health department; served during the World War; aged 51; died, April 28.

Junius V. Talley, Nashville, Ga.; Kentucky School of Medicine, Louisville, 1894; for many years mayor of Nashville; formerly mayor of Milltown; aged 67; died, April 19, in a hospital at Waycross of diabetes mellitus following transurethral prostatic resection.

Harmon Clyde Wolfe, Grand Rapids, Mich.; Detroit College of Medicine, 1905; member of the Michigan State Medical Society; county coroner; for many years on the staff of St. Mary's Hospital; aged 62; died, April 11, of coronary occlusion and sclerosis.

Charles Emerson Libbey, East Hardwick, Vt.; Boston University School of Medicine, 1897; member of the Vermont State Medical Society; served during the World War; of prostatictomy; died, April 8, in the Copley Hospital, Morrisville, of prostatictomy.

Albert Dickson Patillo Sr., Wichita Falls, Texas; Baylor University College of Medicine, Dallas, 1911; member of the State Medical Association of Texas; past president and secretary of the Wichita County Medical Society; aged 65; died, April 17.

George E. Papadopoulos, Weirton, W. Va.; National University of Athens School of Medicine, Greece, 1909; aged 52; died, April 5, in the Ohio Valley General Hospital, Wheeling, of osteitis of the fourth and fifth lumbar vertebrae and uremia.

Adolph Joseph Shimek, Manitowoc, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1904; member of the State Medical Association of Wisconsin; served during the World War; aged 58; died, April 30, of coronary thrombosis.

George Waterman Fifield Ⓢ Janesville, Wis.; Northwestern University Medical School, Chicago, 1896; served during the World War; aged 67; on the staff of the Mercy Hospital, where he died, April 21, of hypertensive nephritis.

Adolph James Kahn, Los Angeles; Bellevue Hospital Medical College, New York, 1886; member of the California Medical Association; past president of the city and county board of health of Napa, Calif.; aged 82; died, March 29.

Benjamin Burch Parish, Walla Walla, Wash.; University of Louisville (Ky.) School of Medicine, 1910; member of the Tennessee State Medical Association; on the staff of the Veterans Administration Facility; aged 52; died, April 29.

James F. Prendergast, Morton, Pa.; University of Pennsylvania Medical Department, Philadelphia, 1884; at one time on the staff of the White Haven (Pa.) Sanatorium; aged 79; died, March 10, of hypertensive cardiovascular disease.

Pitt Edward Tucker, Buckingham, Va.; Medical College of Virginia, Richmond, 1897; member of the Medical Society of Virginia; served during the World War; on the staff of the Southside Hospital, Farmville; aged 68; died, April 27.

James Anderson Grider, Louisville, Ky.; University of Louisville Medical Department, 1894; aged 67; died, April 14, in the Veterans Administration Facility, Hines, Ill., of lymphosarcoma with metastasis to the liver, spleen and heart.

William Herbert Taylor, Ludington, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1885; member of the Michigan State Medical Society; aged 85; died, April 26, of myocarditis and chronic cystitis.

Archie Currie MacKinnon, Atlanta, Mich.; Detroit College of Medicine, 1895; veteran of the Spanish-American and World wars; aged 66; died, April 22, in the United States Marine Hospital, Detroit, of a streptococcal infection.

John Woolfolk Winston, Norfolk, Va.; University of Virginia Department of Medicine, Charlottesville, 1903; aged 59; on the staff of the Leigh Memorial Hospital and the Norfolk General Hospital, where he died, April 17.

Alex B. Garland, Vernon, Texas; University of Nashville (Tenn.) Medical Department, 1905; member of the Nashville Medical Association of Texas; medical director and owner of the Vernon Sanitarium; aged 59; died in April.

James Thomas McKenna, Troy, N. Y.; Albany Medical College, 1896; member and past president of the city board of education; formerly county physician; aged 75; died, April 17, of chronic myocarditis and arteriosclerosis.

John Embert Willis Ⓢ Worcester, Mass.; Boston University School of Medicine, 1898; aged 64; on the staff of the Hahnemann Hospital, where he died, April 21, of coronary thrombosis and hypertensive heart disease.

Leonard Murray Campbell Parker, Baltimore; Baltimore Medical College, 1900; member of the Medical and Chirurgical Faculty of Maryland; aged 60; died, April 22, in the Mercy Hospital of arteriosclerotic heart disease.

Lee Melford Whitsitt, Dallas, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1909; member of the State Medical Association of Texas; aged 77; died, April 2, of thrombo-angiitis obliterans.

William Williams Ⓢ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; served during the World War; aged 56; died, April 5, of a self-inflicted bullet wound.

Erling Alfred Bothne, Ulen, Minn.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; aged 67; died, April 6, in St. Ansgars Hospital, Moorhead, of cirrhosis of the liver.

Harold F. Walsh, Alamosa, Colo.; Kansas City (Mo.) University of Physicians and Surgeons, 1928; member of the Colorado State Medical Society; aged 40; died, April 16, in Denver of nonepidemic encephalitis.

Albert James McCrea, Southbridge, Mass.; Eclectic Medical Institute, Cincinnati, 1894; member of the Massachusetts Medical Society; on the staff of the Harrington Memorial Hospital; aged 68; died, April 28.

Harry Herbert Hagedorn Ⓢ Sioux City, Iowa; State University of Iowa College of Medicine, Iowa City, 1909; served during the World War; aged 54; on the staff of St. Vincent's Hospital, where he died, April 4.

Charles William Powell, Atlanta, Ga.; Leonard Medical School, Raleigh, N. C., 1910; medical superintendent and owner of the William A. Harris Memorial Hospital; aged 59; died, March 21, of coronary occlusion.

Claudius Ezra Rector, England, Ark.; National University of Arts and Sciences Medical Department, St. Louis, 1912; Eclectic Medical University, Kansas City, Mo., 1914; aged 52; died, April 5, of heart disease.

Charles Ludwig III Ⓢ Newark, N. J.; Bellevue Hospital Medical College, New York, 1888; fellow of the American College of Surgeons; aged 73; died, May 4, of arteriosclerosis and coronary thrombosis.

Adolph G. Mizell, Shelbyville, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1897; member of the Illinois State Medical Society; aged 67; died, April 23.

Frederick L. Riser, Henderson, Colo.; Homeopathic Medical College of Missouri, St. Louis, 1884; aged 80; died, April 28, in the Colorado General Hospital, Denver, of diabetes mellitus with gangrene.

Wilmer Phelps Frazier Ⓢ Carthage, Ill.; Rush Medical College, Chicago, 1897; secretary of the Hancock County Medical Society; served during the World War; aged 74; died, April 26, of pneumonia.

Richard Eugene Windley, Vanceboro, N. C.; University of Maryland School of Medicine, Baltimore, 1903; formerly health officer of Beaufort County; aged 61; died, April 25, of coronary thrombosis.

Lynley George Smith, Philadelphia; Temple University School of Medicine, Philadelphia, 1917; served during the World War; aged 53; died, March 26, of coronary thrombosis and arteriosclerosis.

William Harvey Litchfield, Marblehead, Mass.; Harvard University Medical School, Boston, 1882; member of the Massachusetts Medical Society; aged 84; died, April 2, of hypostatic pneumonia.

Emory A. Didama, Cortland, N. Y.; Syracuse University College of Medicine, 1886; member of the Medical Society of the State of New York; aged 77; died, April 14, of carcinoma of the sigmoid.

Harry Ross Wilson, Shawnee, Kan.; University Medical College of Kansas City, Mo., 1900; National Medical University, Chicago, 1905; served during the World War; aged 60; died, April 19.

John Franklin Ward, Fitzgerald, Ga.; Atlanta College of Physicians and Surgeons, 1907; member of the Medical Association of Georgia; served during the World War; aged 52; died, April 9.

Frank Ray, Chesterhill, Ohio; Starling Medical College, Columbus, 1894; member of the Ohio State Medical Association; aged 72; died, March 24, in the Mercy Hospital, Columbus.

John Lovell Sprague * Providence, R. I.; Harvard University Medical School, Boston, 1893; formerly a member of the school board; aged 68; died, April 25, of acute coronary occlusion.

Frederick Day Candler, Merriam, Kan.; Medico-Chirurgical College of Kansas City, Mo., 1902; member of the Kansas Medical Society; aged 64; died, April 27, of cerebral arteriosclerosis.

Emily Louise Barnes Robinson, Cleveland Heights, Ohio; Homeopathic Hospital College, Cleveland, 1889; on the staff of the Huron Road Hospital, East Cleveland; aged 73; died, April 17.

La Mott Day, West Henrietta, N. Y.; University of the City of New York Medical Department, 1888; member of the Medical Society of the State of New York; aged 76; died in March.

David Taylor Davis, Chattanooga, Tenn.; Vanderbilt University School of Medicine, Nashville, 1888; aged 83; died, April 29, of prostatic hypertrophy and acute retention of the urine.

Herbert Francis Kenny * Waukesha, Wis.; University of Michigan Medical School, Ann Arbor, 1916; served during the World War; aged 51; died, April 14, of coronary thrombosis.

Charles L. O'Brien * Chicago; Rush Medical College, Chicago, 1903; on the staff of St. Francis Hospital, Evanston, Ill.; aged 59; died, April 29, of erysipelas and pernicious anemia.

John William Bowdoin, Bloxom, Va.; College of Physicians and Surgeons, Baltimore, 1876; University of the City of New York Medical Department, 1877; aged 84; died, April 5.

George Clough Lowell, San Anselmo, Calif.; University of California Medical School, San Francisco, 1936; member of the California Medical Association; aged 45; died, March 27.

Frank Thomas MacLeod, New Waterford, N. S., Canada; Dalhousie University Faculty of Medicine, Halifax, 1919; aged 58; died, March 9, in the Sydney City Hospital, Sydney, N. S.

William Davis Hope, Lockhart, S. C.; University of Maryland School of Medicine, Baltimore, 1887; member of the South Carolina Medical Association; aged 73; died, April 27.

Tib Newberry Goff, Kenova, W. Va.; Kentucky University Medical Department, Louisville, 1904; veteran of the Spanish-American and World wars; aged 61; died, April 30.

John Frevola, Brooklyn; University and Bellevue Hospital Medical College, New York, 1920; on the staff of the Holy Family Hospital; aged 44; died, April 29, of lobar pneumonia.

Henry Reuben Plum, Lancaster, Ohio; Starling Medical College, Columbus, 1898; member of the Ohio State Medical Association; aged 71; died, April 2, of coronary thrombosis.

William Anthony Cimillo, New York; Eclectic Medical College of the City of New York, 1905; member of the Medical Society of the State of New York; aged 58; died, March 27.

John Henry Whittaker, Las Animas, Colo.; University Medical College of Kansas City, Mo., 1901; served during the World War; aged 64; died, April 4, of valvular heart disease.

John William Epler, Kearney, Mo.; Jefferson Medical College of Philadelphia, 1883; member of the Missouri State Medical Association; aged 83; died, April 23, of arteriosclerosis.

John William Watson, Henderson, Ky.; Kentucky School of Medicine, Louisville, 1894; aged 76; died, April 13, in the Boehne Hospital, Evansville, Ind., of pulmonary tuberculosis.

S. Percival Wells, Holly Hill, S. C.; Atlanta College of Physicians and Surgeons, 1904; formerly mayor of Holly Hill; aged 64; died, April 10, of coronary stenosis and nephritis.

John Anthony Manzella * Buffalo; Regia Università degli Studi di Padova Facoltà di Medicina e Chirurgia, Italy, 1932; aged 32; died, April 19, of pulmonary tuberculosis.

Charles Edward Lynch, Boston; Tufts College Medical School, Boston, 1923; member of the Massachusetts Medical Society; aged 40; died, April 13, of coronary thrombosis.

William A. Palmer, Corpus Christi, Texas; University of Louisville (Ky.) Medical Department, 1875; Confederate veteran; aged 92; died, April 9, of hypostatic pneumonia.

Abram N. Garver, Lorain, Ohio; University of Wooster Medical Department, Cleveland, 1879; aged 82; died, April 26, in St. Joseph's Hospital of injuries received in a fall.

Hall Alvord Kellogg, New York; University of Rochester School of Medicine, 1935; resident to the Lincoln Hospital; aged 30; died, April 23, of acute coronary occlusion.

James Melvin Ward, St. Petersburg, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; aged 72; died, April 10, of atrophic cirrhosis of the liver.

Gustav Nils Nilsson * Omaha; University of Nebraska College of Medicine, Omaha, 1928; aged 45; died, April 5, in the Clarkson Hospital of perforated gastric ulcer.

Alfred Burt Pickering, Maplesville, Ala.; University of Alabama School of Medicine, Mobile, 1911; aged 52; died, April 9, in a hospital at Selma of heart disease.

George M. Agan, Owatonna, Minn.; Hospital College of Medicine, Louisville, Ky., 1886; member of the Iowa State Medical Society; aged 79; died, March 14.

Arthur B. Lathrop, Swanton, Ohio; Starling Medical College, Columbus, 1882; Bellevue Hospital Medical College, New York, 1883; aged 82; died, April 23.

Warren A. Rosser, Atlanta, Ga.; Atlanta Medical College, 1881; for many years a member of the Monroe County Board of Education; aged 80; died, March 26.

Charles M. Marnes, Rouses Point, N. Y.; College of Physicians and Surgeons of Chicago, 1886; formerly postmaster; aged 75; died, March 27.

Charles C. Mullin, Syracuse, N. Y.; Syracuse University College of Medicine, 1898; aged 66; died, April 15, of cerebral hemorrhage and arteriosclerosis.

James Henry Townsend, Collinwood, Tenn.; University of Tennessee Medical Department, Nashville, 1892; aged 70; died, April 29, of nephritis.

Carl F. Schiedel, Milwaukee; Wisconsin College of Physicians and Surgeons, Milwaukee, 1894; aged 67; died, April 29, of carcinoma of the colon.

James Chauncey Fitch, New York; University of the City of New York Medical Department, 1884; also a dentist; aged 75; died, April 22.

George Denison Clift, Purdy Station, N. Y.; University of the City of New York Medical Department, 1878; aged 88; died, April 7, of senility.

William C. Warren, Atlanta, Ga.; Atlanta Medical College, 1890; member of the Medical Association of Georgia; aged 69; died, April 23.

Verner Ashton Hartman, Post, Texas; Memphis (Tenn.) Hospital Medical College, 1908; aged 54; died, April 8, in a hospital at Lubbock.

Benjamin Franklin Hutchins, Portsmouth, Va.; Leonard Medical School, Raleigh, 1902; aged 63; died, April 2, in a hospital at Norfolk.

James W. Nixon, Gonzales, Texas; Medical College of Louisiana, New Orleans, 1880; aged 83; died, March 5, in the Holmes Hospital.

Karekeen Hekimian Sewny, New York; University of the City of New York Medical Department, 1875; aged 86; died, March 16.

Joseph M. Sanders, Scurry, Texas; Memphis (Tenn.) Hospital Medical College, 1900; aged 67; died in April of carcinoma of the throat.

William Charles Shriner, Cincinnati; Eclectic Medical Institute, Cincinnati, 1898; aged 66; died, April 28, of carcinoma of the ileum.

Harry Kotler, Chicago; University of Illinois College of Medicine, Chicago, 1933; aged 29; died, March 31, of miliary tuberculosis.

William Penning Stern, Milwaukee; Rush Medical College, Chicago, 1923; aged 40; died, April 1, of myelogenous leukemia.

George W. Buckmaster, Beaver, Okla. (licensed in Oklahoma Act of 1908); aged 81; died, April 18, of cerebral hemorrhage.

A. B. Wood, Quitman, Ark. (licensed in Arkansas in 1903); aged 69; died, April 6, of dilatation of the heart and myocarditis.

Henry Bley, Coffeeville, Miss.; Medico-Chirurgical College of Philadelphia, 1914; aged 52; died, March 9.

Correspondence

THE DILEMMA CONCERNING DIETETIC CELLULOSE

To the Editor:—A dilemma, apparently more confusing than the one regarding vitamin C requirements which Stefansson referred to in *Science* (89:484 [May 26] 1939), has arisen in recent years because of conflicting reports concerning the effect of cellulose in the diet. Thus, Cowgill and Sullivan (*THE JOURNAL*, March 18, 1933, p. 795) concluded that the laxative effect of food pulp is proportional to the amount of fiber escaping destruction in the digestive tract. Williams and Olmsted (*J. Nutrition* 11:433 [May] 1936), however, concluded that the laxative effect of the cellulosic constituents in the diet is proportional to the percentage destroyed in the digestive tract. Similarly some investigators, such as Frey, Harding and Helmbold (*M. J. & Rec.* 127:585 [June 6] 1928), reported that pure cellulose served quite well as a laxative, but Bastedo (*Materia Medica, Pharmacology and Therapeutics*, ed. 4, Philadelphia, W. B. Saunders Company, 1938) stated that he found cellulose to be ineffective. And again, Harriet Morgan (*THE JOURNAL*, March 31, 1934, p. 995) reported that the ingestion of pure cellulose caused increased excretion of nitrogen and minerals, while Adolph and Wu (*J. Nutrition* 7:381 [April] 1934) found that inert bulky materials had no significant effect on protein digestibility.

All these studies involved or included the use of human subjects. The study of Frey, Harding and Helmbold, however, already indicated that their type of cellulose was not as effective in elderly subjects as in children, and it would seem that effectiveness in the more difficult instances presented by elderly persons would have served as a better criterion of the laxative value of their particular product. The results arrived at by Williams and Olmsted were obtained by study of the separate fate of the lignin, cellulose and hemicellulose of some substances as distinguished from the fate of simple crude fiber in the digestive tract, but it is my impression that the use of other materials, such as ground kapok (a highly lignified but relatively smooth and bulky fiber) and psyllium seed husks (mainly hemicellulose of a type that seems to resist breakdown better than the hemicellulose of most foods), would have yielded data supporting the conclusion of Cowgill and Sullivan.

The use of No. 300 cellophane as cellulose in Harriet Morgan's study seems to make it doubtful whether her results would apply to the use of any more satisfactory type of cellulose. In our study of the effect of No. 300 cellophane (Hoelzel, Frederick, and Da Costa, E.: *Am. J. Digest. Dis. & Nutrition* 4:23 [March] 1937), in which we referred to this as granular cellulose, clear scratch marks as well as a tendency to polyp formation were found in the colons of three of seven rats. Hence this form of cellulose was regarded as too irritating for human use. However, I used ground No. 150 Dupont cellophane daily for about two years without any indication of irritation. No. 150 cellophane is only half as thick as No. 300. Some individuals nevertheless also found No. 150 cellophane to be quite irritating. A flakelike product made from artificial (cellophane-like) straw proved to be more satisfactory, but its use was abandoned after it was found that the manufacturers used a secret, although apparently inert, finishing material. No. 150 cellophane also was not always obtainable and was high in price. I therefore tried No. 300 cellophane with the addition of a small amount of petrolatum to avoid possible irritation. The results at first seemed fairly satisfactory, but after three weeks the use of this cellophane had to be abandoned because of severe pain from mechanical irritation. Since then,

No. 150 cellophane as well as other previously nonirritating forms of cellulose could not be tolerated. The results obtained in the five day tests performed by Harriet Morgan may therefore have been largely the consequence of mechanical irritation.

These comments indicate the unsettled state of expert opinion regarding the effect of the nonnutritive part of the diet, which was already well under investigation before any vitamins were discovered. In view of this, how can one expect any general agreement in the near future concerning vitamin C or other nutritive requirements?

FREDERICK HOELZEL, Chicago.

Department of Physiology, University of Chicago.

EXERTION AND CORONARY THROMBOSIS

To the Editor:—I have just noticed the comments by Master in *THE JOURNAL*, April 22, on coronary thrombosis. It is, of course, hard to get at the facts as to the origin of coronary occlusion from either the experimental or the postmortem approach.

In an analysis of 100 private patients carefully studied, I was able to find 17 per cent who had had an occlusion within twenty-four hours of definitely unusual and, frequently, rather extreme exertion. For example, one of my patients, a salesman who was not used to physical strain, had been having stenocardia of effort, although it was not severe. At 6 a. m., with a temperature of 7 degrees below zero, he attempted to crank his car, which had failed to start. After a great deal of strain he did succeed, but in an hour or two he was complaining of some indigestion. At 5 p. m. he collapsed with a typical coronary occlusion.

Another, a real estate operator, who was flabby, 54, and drank several bottles of beer every day, attempted to extricate his trunk from the trunk room of an apartment house. It was finally done with considerable effort and obvious overstrain. Four hours later he went to a nearby hospital with substernal pain and was given 1 grain (0.065 Gm.) of codeine without relief. I saw him four hours after that in a severe and typical attack of coronary thrombosis.

There are seventeen such cases in my series and I should like to have an explanation of the relationship—if it is not that of overstrain—facilitating the development of a thrombus.

The basic cause of these occlusions is, of course, atheromatosis. I myself have never seen at postmortem examination a single case of coronary occlusion in which the thrombus was not at the site of a greatly roughened and, frequently, narrowed area in the coronary tree. Is it not logical to assume that during considerable strain, as the result of the breaking of a portion of the hard atheromatous area or the rupture of a tiny subintimal vessel, there may be present tissue substance which is the nucleus of platelet agglutination leading to the formation of thrombosis? A small subintimal hemorrhage or tear in the hardened wall may not be demonstrable by the time a postmortem examination is done. Further, it is well established that one's physiologic response to exercise depends a great deal on one's status as to physical stamina and "training," so to speak. The well trained athlete shows relatively little changes in pulse rate and blood pressure as compared to a sedentary individual with no physical build-up. It is also established that with severe sudden physical exertion there is sometimes an extreme rise of blood pressure but more often a considerable drop after an initial rise. It is this fall of pressure that obviously can produce a disturbance in the coronary flow, and I have long contended that in the sedentary individuals who exert themselves overmuch one can produce—with a combination of fall in blood pressure and an unduly accelerated heart—a very possible coronary stasis.

If this assumption is tenable, then the small nucleus of platelet agglutination in the presence of stasis can be said to bring about the thrombosis.

I deny that coronary thrombosis occurs as frequently in the physically active persons of equal age as in those who lead sedentary lives. I have presented talks on coronary disease in some of the smaller localities in Michigan, particularly in the farm belt, and frequently some of the best physicians in that area state that they never see any cases of coronary occlusion. Some cases obviously are missed, but most clinical types are so striking that it is not possible to miss all of them. During ten years' work in the heart clinic of the outpatient department of Harper Hospital I was able to find only two acute cases of coronary occlusion. At the same time I was seeing well over 100 cases in my private office. I believe that one of the reasons for this difference may be the difference in physical response to exercise between the two groups who are using their muscles every day and those who use their muscles little in the routine of daily life.

WARREN B. COOKSEY, M.D., Detroit.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ORANGE JUICE AND VITAMIN C

To the Editor:—Does orange juice lose in vitamin content if squeezed from the orange at night and kept in a lightly covered glass in a refrigerator to be served at breakfast the next morning?

M.D., Wisconsin.

ANSWER.—Because vitamin C is readily destroyed by oxidation, it was commonly thought for several years that it would be good practice to consume citrus juices as soon as possible after their preparation. In an investigation of the vitamin C content of orange juice performed in the laboratories of the Bureau of Home Economics of the U. S. Department of Agriculture (Daniel, Esther P.; Kennedy, Mary H., and Munsell, Hazel E.: *Relative Vitamin C Content of Orange and Tomato Juices Determined Chemically and Biologically, J. Home Econ.* 28:470 [Sept.] 1936), a loss of about 10 per cent of the vitamin C of freshly extracted orange juice that had stood about six hours in a covered container in a refrigerator was observed. It was thought that the time of standing determined the extent of loss, and the following warning appeared in a boxed statement of practical significance of results at the end of the report: "Since juices lose their scurvy-preventing power on standing, the common household routine of preparing juice in the evening for breakfast should not be practiced." More recently, however, Munsell and her collaborators (McElroy, Olive E.; Munsell, Hazel E., and Stienbarger, Mabel C.: *Ascorbic Acid Content of Tomatoes as Affected by Home Canning and Subsequent Storage, and of Tomato Juice and Fresh Orange Juice as Affected by Refrigeration, ibid.* 31:325 [May] 1939) have repeated the observations on orange juice, using an improved technique, and have found no appreciable loss of ascorbic acid (vitamin C) in orange juice stored for twenty-four hours in loosely covered glass jars in a refrigerator at temperatures of approximately 40 to 45 F.; i. e., safe refrigeration temperatures. It is reported that there was no difference in the results when the juice was strained through cheesecloth or through a wire sieve.

Evidence obtained from experiments performed at the Connecticut Agricultural Experiment Station, at the request of the Council on Foods (THE JOURNAL, June 10, p. 2420), also shows that fresh orange juice retains as much as 97.6 per cent of its vitamin C activity after storage for twenty-four hours in a loosely stoppered flask in a refrigerator.

It is thus clear that fresh orange juice loses little vitamin C potency on standing in the refrigerator if the juice is kept in a covered container to avoid access to air.

MECHANISM OF PREMATURE EJACULATION

To the Editor:—What connection is there between ejaculation praecox and the sympathetic nervous system? What evidence is there that the nervous reflex of the erector mechanism in man belongs to the parasympathetic and the ejaculator reflex to the sympathetic system? What would be the better drugs to use in ejaculation praecox with a hyperexcitable sympathetic?

M.D., Washington, D. C.

ANSWER.—Premature ejaculation, like normal ejaculation, is essentially a reflex reaction. The premature state occurs frequently in normal men both early and late in life. It occurs also in organic disease of the central nervous system and of the sympathetic nervous system and in deficiencies of the sex glands. Voluntary inhibitions as well as voluntary excitations are controlling factors in the sexual act. The process in premature ejaculation is a utilization of the sympathetic and cerebrospinal pathways in such a way that there is a rapid summation instead of a gradual summation of stimuli. Thus in cases of emotionally unstable males, of infrequent copulation, of defects in the secretion of the sex glands and of diseases of the lumbosacral spinal cord one finds instances of premature ejaculation. If sexual excitation occurs as a result of afferent stimulation (visceral organs and sexual apparatus), suggestion and sensual associations and desires it follows that premature ejaculations may result from a deficiency of these factors as well as from a hyperirritable ejaculatory center in the lumbar cord (sympathetic).

Erection is brought about by engorgement of the corpora cavernosa, the result of parasympathetic stimulation. It is well known that sensory impressions by way of the optic, olfactory, and auditory nerves as well as touch may cause erection. Erection may also be induced by stimulation of the glans penis. The pathways for erection are as follows: genital corpuscles in the glans penis, the dorsal nerve of the penis, common pudendal nerves into the cord and the medullated erecting nerves (of the second, third and fourth sacral cords) from the cord, which finally form the cavernous plexus and gray unmedullated cavernous nerves conveying vasodilator impulses to the corpora cavernosa.

The ejaculatory reflex is mediated by the following: rubbing of the glans penis leading to a summation of excitatory stimuli in the spinal cord carried inward by way of the dorsal nerves of the penis and the common pudendal nerves. In the cord two reflex centers are activated, one in the upper lumbar cord and the other in the lower sacral center. From the upper lumbar cord rami communicantes pass by way of the hypogastric nerves to the plexus, from which the smooth unstriated muscles of the ductus deferens, seminal vesicles and prostate derive innervation. The lower sacral center stimulates the striated muscle fibers of the compressor of the urethra and the bulbocavernosus and ischiocavernosus to clonic contraction. Mydriasis, elevation of the blood pressure, increase in the pulse rate and sweating accompany ejaculation.

There are no specific drugs for premature ejaculation. Bromides and chloral may be used for emotional states, while strychnine may be used in organic lesions of the lumbosacral cord.

FEVER THERAPY IN RHEUMATIC FEVER

To the Editor:—What information is available on fever therapy in the treatment of rheumatic fever or its complications?

C. L. Carter, M.D., Ottawa, Ill.

ANSWER.—In 1933 Sutton and Dodge (*J. Pediat.* 3:813 [Dec.] 1933) treated patients suffering from Sydenham's chorea with fever induced by intravenous injections of typhoid-paratyphoid vaccine; active carditis was found not to be a contraindication to such therapy; indeed it seemed to be benefited. Later Sutton and Dodge reported results in the treatment of eighteen patients with active rheumatic carditis by means of fever therapy; the fever was induced by typhoid vaccine in sixteen cases, by radiant energy in two cases (*J. Pediat.* 6:494 [April] 1935; *J. Lab. & Clin. Med.* 21:619 [March] 1936). From four to fourteen fever sessions were given over a period of from five to twenty-six days. Generally only a few fever sessions were required, each session being from two to five hours at from 105 to 106 F. In all cases clinical signs of activity of the carditis "completely subsided" within ten to fourteen days after treatment. In some cases relapses occurred after several months. It was concluded that fever therapy did not harm patients with subacute or inactive rheumatic carditis; and that it apparently benefited them, at least temporarily. Further observation was required to determine whether it had any permanent beneficial effect on rheumatic carditis and its complications.

The advantages of artificial fever induced by machines such as the Kettering hypertherm over the less controllable fevers induced by injections of triple typhoid vaccine were also stressed by Barnacle, Ewalt and Ebaugh (*THE JOURNAL*, June 13, 1936, p. 2046), who treated thirteen cases of chorea. In seven, in which there were cardiac complications, the fever sessions were well tolerated. No detailed comments were made as to the effect of the fever sessions on the carditis.

These preliminary observations have been confirmed by the more recent studies of Simmons (*Ann. J. M. Sc.* 194:170 [Aug.] 1937), Kendall and Simpson (*Ohio State M. J.* 33:1097 [Oct.] 1937), Williams (*South M. J.* 30:1080 [Nov.] 1937) and Dunn and Simmons (*Ann. Int. Med.* 11:1600 [March] 1938). In a total of about fifty additional cases of "acute rheumatic fever" and of active rheumatic endocarditis with or without chorea, fever treatment was given. Generally within four to seven weeks the signs of active carditis (fever, tachycardia, first degree heart block) disappeared. Leukocyte counts and sedimentation rates became normal in many cases. In three cases mitral murmurs disappeared (Kendall and Simpson). Dunn and Simmons noted the disappearance of pericardial effusion. In a few cases improvement had not occurred. Patients generally received an average of from five to nine fever sessions (each from two and a half to four hours at from 103 to 106 F.).

Follow-up studies in most of these cases are incomplete; in some cases they were made two years or less after treatment. In a number of cases no recurrences of active symptoms had taken place and they were classified as apparently cured; in some cases recurrences had occurred. There is therefore a general agreement that the immediate effects of fever therapy on acute rheumatic fever and on active rheumatic carditis (with or without chorea) are usually beneficial. However, since rheumatic fever and carditis are subject to a well marked tendency to spontaneous remissions, one cannot yet make any final conclusions as to the permanence of the relief from fever therapy and the ability of fever therapy to heal or prevent the cardiac and other complications of rheumatic fever. Because of these good preliminary results and because of the limited value of standard methods of treatment in these conditions, a trial of fever therapy seems justified, but only if it can be applied by those entirely familiar with the technic of its application and with its dangers.

LIGHTNING PAINS AND CEREBROSPINAL SYPHILIS

To the Editor:—A man aged 50, married, had both legs amputated about 8 inches below the knees, in 1903, following freezing. About seven years later (in 1910), he began to have shooting pains in both stumps. These pains became progressively more severe over a period of time and did not respond to any of the usual analgesics. In 1922 in an urban medical center, a positive Wassermann reaction of the blood and spinal fluid was found. There followed eight years of intensive antisyphilitic treatment, including arsphenamine, nearsphenamine, bismuth compounds, pyrotherapy and three injections of trypanamide. The Wassermann reaction of the blood and spinal fluid became negative but there was no reduction in the severity and recurrence of the pains in the stump. The last Wassermann reaction of the spinal fluid, in February 1937, was negative. Since then there have been recurrent attacks of severe pains in both stumps, radiating up the thighs and hips, coming on every two to three months and lasting from one to two days. During one attack the oral temperature was 103 F. Six intravenous injections of trypanamide 2 Gm. have been given in the past weeks, only to have the pains recur in greater severity and be controlled only by narcotics. Physical examination is essentially negative except for absence of the lower extremities as noted and inequality of the pupils with a sluggish reaction of the left eye to light.

M.D., California.

ANSWER:—In cases of this sort in which the lightning pains, presumably as a result of involvement of the central nervous system by syphilis, have not disappeared in spite of intensive antisyphilitic therapy, it is of course necessary that the patient be studied thoroughly in order to rule out the possibility that the symptoms may be caused by something other than syphilis. Such a study should include a search for foci of infection, an x-ray examination of the spine and an effort to determine whether any other medical or orthopedic condition including circulatory disturbances, bone spur or a neuroma in the stump itself might be active.

If all such medical search proves fruitless and the condition seems to be almost certainly the result of syphilis, it would seem unwise to continue intensive antisyphilitic therapy at this point, since it has proved of little avail up to now. In fact, prolonged administration of the arsenical drugs in full dosage is frequently apt to incite tabetic pain in such a case.

Efforts must now be directed toward raising the general well-being of the patient and encouraging him mentally. Change to

a warm climate, avoidance of over strenuous exertion and the occasional judicious use of mild sedatives are in order. Colonic irrigations are sometimes helpful and anticonstipation regimens are useful; irradiation with ultraviolet rays and tonics to build up the general physical health of this patient are also desirable. If nothing else avails, a more strenuous procedure, such as fever therapy, should seriously be considered, provided the physical condition of the patient permits.

The use of narcotics for the relief of any painful symptom of tabes, including crises, cannot be too vigorously condemned. The combination of tabes and morphinism is a therapeutically impossible one and inevitably leads to deterioration.

QUESTIONABLE CONJUGAL SYPHILIS AND CHILDBIRTH

To the Editor:—A white woman aged 26, married, missed three periods. She presented the usual signs and symptoms of a three months pregnancy. She stated that she had been pregnant about a year before but had had an induced abortion performed at two months. She is now anxious to have a child. She also stated that she had been told that she had some form of female trouble in the past. She does not know the type. She is positive, however, that four years before her husband had an acute gonorrheal infection. She has also had several attacks of cystitis in the past three years. She was never told that she had pyelitis. Her history otherwise is negative. She further stated that her husband had been told that he had syphilis. When questioned concerning this, she stated that on repeated blood examinations he had been told that the laboratories reported a two plus reaction. He has had many tests taken and always a two plus is reported. The husband insists that he has never had treatment of any kind and has never had a primary or secondary rash. He had refused to take treatment. The patient has also had several blood tests taken and in her case they have always been reported negative. Physical examination showed a well developed woman about three months pregnant. Blood counts, urinalysis and in general her examinations are entirely negative. A Wassermann test was reported negative. Her pregnancy progressed normally until the fifth month when she began to complain of frequent attacks of severe pains. These attacks of pain were always due to uterine contractions. She also had frequent attacks of cystitis. Wassermann and Kahn tests were repeated and again were reported negative. Beginning at about the sixth month of pregnancy the fetal heart tones could not be heard. She did think she felt motion, however. She continued feeling bad and seldom spent a full day out of bed. She miscarried the seventh month. The fetus was covered with a film and the skin was macerated and peeled, leaving the muscle tissue bluish red and exposed. Since this family lived quite a distance from a pathologist an autopsy was not done. On the basis of this history I would greatly appreciate your opinions on the following questions: 1. Why would the husband get a repeated two plus serologic reaction when he has never had any antisyphilitic therapy? Is he really syphilitic? 2. If we classify the husband as syphilitic, what is the significance of the repeated negative serologic reactions in her case? 3. Are we justified in classifying this stillbirth as due to syphilis? 4. What suggestion would you make as to a future pregnancy, since she is anxious to have a child? 5. How can we definitely rule out syphilis?

M.D., West Virginia.

ANSWER.—1. Much depends on the types of serologic reactions and on who did them. Certain persons may show such a reaction but unless there is evidence of syphilis on physical examination and lumbar puncture it would not justify such a diagnosis.

2. Perhaps the wife does not have syphilis.

3. No, not without more satisfactory evidence.

4. Follow her case through carefully. Moreover, insist on a thorough, complete check of the husband.

5. A diagnosis of syphilis in the wife is not justifiable if thorough physical examination and repeated serologic blood reactions are all negative. This is particularly true in the absence of stronger evidence of the disease in the husband.

FURUNCULOSIS OF SCALP IN INFANTS

To the Editor:—I have seen two cases of boils of the scalp in newborn babies who have been given whooping cough serum. Whooping cough did not develop in either baby although the mothers of both had whooping cough when the babies were born. One mother also has diabetes. The boils developed about one month after birth. I have used Sauer's vaccine made by Eli Lilly & Co. Do you think the serum had anything to do with the boils?

Leland C. Pomainville, M.D., Wisconsin Rapids, Wis.

ANSWER.—Boils of the scalp (furunculosis) in young infants frequently result from pillows, excessive perspiration of the head, lack of sufficient ventilation in the infant's crib, lack of care of the scalp, "cradle-cap" and the like.

The vaccine per se could not cause boils of the scalp. The rubber vial cap of the vaccine bottle should always be thoroughly sterilized by being rubbed with pure alcohol (70 or 95 per cent) on a sterile cotton or gauze sponge. The syringe and needles for pertussis vaccine (Sauer) should be sterilized by heat, preferably in the oven (at 250 F. for one hour) or the submerged plunger, barrel and needles should be boiled in pure (preferably

distilled) water for ten minutes and cooled before use. The use of chemicals (alcohol and the like) for sterilizing the syringe and needles is hazardous, chiefly because ordinary rubbing alcohol is not antiseptic and because pure ethyl alcohol is seldom allowed to act sufficiently long to effect sterilization of the apparatus. "When the heat-sterilized syringe is reused without resterilization, as is customary when more than one child is injected, the used needle should be cautiously replaced with a sterile one, without the tip of the syringe being touched. To avoid contamination of vaccine with resultant local infection, only the very end of the plunger should be touched as the syringe is being filled and discharged." (THE JOURNAL, January 28, p. 306).

EXPOSURE TO ROENTGEN RAYS AND CYSTIC MASTITIS

To the Editor:—A woman aged 25, always well, started to work in a busy x-ray laboratory. After seven months she started to menstruate almost continuously and was forced to stop work at the end of one year. A dilation and curettage at that time resulted in a rather severe hemorrhage but no other manifestations. She gradually regained her health and was married. At 31, four years after marriage, she noticed a lump in her breast, which grew rather rapidly and was painful, especially at the period. It was removed three months ago and found to be a fibrous tumor with mastitis. Now she has more pain than ever, especially at the period. The breast is normal to palpation. There have been no pregnancies. There is evidently an endocrine unbalance here. Could you explain it to me.

B. F. Cook, M.D., Rutland, Vt.

ANSWER:—It is almost certain that the employment in the x-ray laboratory had nothing to do with the lump in the breast, which developed at least four years after she left the laboratory. The condition in the breast was most likely chronic cystic mastitis. This abnormality as well as the continuous bleeding which the patient had a few years ago may have been due to the presence of excessive amounts of estrogen in the body. An attempt may be made to decrease it by means of testosterone propionate, the male sex hormone. In order to obtain any satisfactory results, 25 mg. of testosterone propionate should be given hypodermically three times a week for a month or longer. However, caution must be used because of the possibility of producing virilizing symptoms as a result of this therapy.

METHYLENE BLUE IN CARBON MONOXIDE AND CYANIDE POISONING

To the Editor:—Kindly explain the action of methylene blue in carbon monoxide and cyanide poisoning. What is the strength of the solution used.

M.D., New Jersey.

ANSWER:—Methylene blue acts as a weak oxidizing agent in the tissues. In the blood it converts hemoglobin into methemoglobin. Methemoglobin tends to combine with cyanides and thus to diminish their poisonous effects. In carbon monoxide poisoning, on the contrary, the formation of methemoglobin further decreases the oxygen carrying capacity of the blood. It is therefore not helpful but harmful.

SULFANILAMIDE AND CHRONIC PROSTATITIS

To the Editor:—Have you any information about the use of sulfanilamide in chronic prostatitis following gonorrhea when the invading organisms are staphylococci, nonhemolytic streptococci, colon or diptheroid bacilli and the like?

M. H. Axilrod, M.D., Atlantic City, N. J.

ANSWER:—Sulfanilamide has been used successfully in the treatment of chronic prostatitis following gonorrhea, but it should be remembered that this drug is of value only as an adjunct to systematic local prostatic treatment. Sulfanilamide is excreted in the prostatic secretion and is present in sufficient quantities to provide action against the invading organisms, but it is also necessary to provide drainage. The best known method to provide this drainage is gentle but firm massage once a week. Periodic dilations may also be used. The recommended dosage of sulfanilamide varies with the individual and with his degree of activity. The ordinary ambulatory patient should receive from 30 to 40 grains (2 to 2.6 Gm.) daily for not more than a week or ten days together with an equal amount of sodium bicarbonate. The well known toxic manifestations of the drug must always be anticipated.

PROETZ POSITION

To the Editor:—For several years I have been thinking that I have ethmoid sinusitis of a mild nature. I am particularly interested in learning the exact position of the head as described by Proetz. Is amphetamine (benzedrine) solution 2 per cent at all comparable to the ephedrine and isotonic saline solution used for this purpose? Could you name several of the best books on the ear, nose and throat at present?

M.D., Vermont.

ANSWER:—In the Proetz position the patient lies on his back on a table with his head hanging over the end and hyperextended so that a line from the chin to the forehead is perpendicular.

Amphetamine is put up in a 1 per cent oil solution, which would not be suitable for treatment. A substitute for ephedrine, in case of idiosyncrasy, is neosynephrin, a $\frac{1}{8}$ per cent or $\frac{1}{16}$ per cent solution in physiologic solution of sodium chloride.

There are several excellent textbooks on the ear, nose and throat, among them those written by Jackson and Coates, Ballenger and Lederer.

NO MERCURY ABSORPTION THROUGH RUBBER GLOVE

To the Editor:—Is it possible for mercury to be absorbed through a rubber glove by an attendant giving a mercury inunction?

Andrew Grinley, M.D., St. Paul.

ANSWER:—There is no absorption of mercury through a rubber glove used by an attendant giving a mercurial inunction. There is the possibility that the attendant may absorb some of the mercury through the respiratory tract and in this way evidence some manifestation of mercurialization but, if a rubber glove is intact, absorption of mercury through it is not possible.

SMOKING DURING PREGNANCY AND LACTATION

To the Editor:—Does smoking have any effects (good or bad) on mothers during pregnancy or on the baby during this period or afterward? The question came up in a high school class and the teacher asked my opinion. I had none based on scientific facts but I said that I knew where I could get such an opinion.

M.D., Nebraska.

ANSWER:—Smoking does not have any good effects on the mother during pregnancy; however, clinical experience would indicate that a moderate use of tobacco is not harmful to the mother or to the baby. When a woman smokes excessively it is usually suggested that she decrease her smoking during pregnancy and particularly during the nursing period.

Many physicians feel that the nicotine in tobacco may have a deleterious effect on the baby, but there is little scientific evidence to substantiate this view. Nicotine, however, does pass through into the mother's milk, so that excessive smoking may result in toxic amounts of nicotine being absorbed by the child.

NATIONAL ASSOCIATION OF FEVER THERAPY TECHNICIANS

To the Editor:—What is the standing of the National Association of Fever Therapy Technicians?

M.D., Illinois.

ANSWER:—This organization is promoted by a Chicago advertising agency and has no recognition from the American Medical Association, the American Congress of Physical Therapy, the American Physiotherapy Association or the American Registry of Physical Therapy Technicians.

The association proposes to certify through membership examinations those who are qualified as fever therapy technicians. There would seem to be little need for such an organization as this and, were there a need, sponsorship should be by interested professional groups.

BISMUTH COMPOUNDS WITH AMEBICIDES

To the Editor:—Will you please inform me whether bismuth subnitrate or subcarbonate in large doses, from 30 to 60 grains (2 to 4 Gm.), when given in conjunction with chiniofon or vioform, is compatible in the treatment of amebic dysentery? What changes, if any, would take place in either drug? Would the bismuth coating lessen the efficacy of the remedy used?

M.D., California.

ANSWER:—The use of large doses of bismuth subcarbonate or bismuth subnitrate is compatible with the use of chiniofon or vioform in the treatment of amebic dysentery if the drugs are given by mouth. If a retention enema of one of these drugs is given, the coating of the bismuth compound might interfere with its local action. The bismuth will not change the action of the drugs when they are given by mouth.

EXAMINATION AND LICENSURE
Medical Examinations and LicensureCOMING EXAMINATIONS
NATIONAL BOARD OF MEDICAL EXAMINERS
SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, July 15, page 254.

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 18-20. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

ARKANSAS: Medical (Regular). Little Rock, Nov. 9-10. Sec., Dr. D. L. Owens, Harrison. Medical (Eclectic). Little Rock, Nov. 9-10. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock.

CALIFORNIA: Written examinations. Los Angeles, Aug. 7-10, and application is based on a state certificate or license issued ten or more years before filing application in California, Los Angeles, August 7, and San Francisco, Nov. 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT: Medical Endorsement. Hartford, July 25. Sec., Dr. Thomas P. Murdock, 147 West Main Street, Meriden. Basic Science. State Board of Healing Arts, 1895 Yale Station, New Haven. Address Box 786, Tampa.

FLORIDA: Jacksonville, Nov. 13-14. Sec., Dr. William M. Rowlett, Georgia. Atlanta, Oct. 10-11. Joint-Sec., State Examining Boards, Idaho. Boise, Oct. 3-4. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, State Capitol Bldg., Boise.

ILLINOIS: Chicago, Oct. 17-19. Superintendent of Registration, Mr. Springfield. Indianapolis, June 18-20. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

KENTUCKY: Louisville, Dec. 5-7. Sec., State Board of Health, Dr. A. T. McCormack, 620 S. Third St., Louisville.

MARYLAND: Baltimore, Dec. 12-13. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MICHIGAN: Lansing, Oct. 11-13. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 100 W. Allegan St., Lansing.

MINNESOTA: Basic Science. Minneapolis, Oct. 3-4. Sec., Dr. J. Charley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. Medical. Minneapolis, Oct. 17-19. Sec., Dr. J. P. Peter St., St. Paul.

MISSISSIPPI: Reciprocity. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whittlesey, Helena, Oct. 3-4. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

MONTANA: Helena, Oct. 3-4. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, 1009 State Capitol Bldg., Lincoln.

NEBRASKA: Lincoln, Oct. 3-4. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEVADA: Reno, Oct. 17-18. Sec., Dr. Earl S. Hallinger, 28 Sena Plaza, Santa Fe.

NEW HAMPSHIRE: Concord, Sept. 14-15. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, Oct. 17-18. Sec., Dr. Le Grand Ward, 135 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 9-10. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York and Syracuse, Sept. 18-21. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

OKLAHOMA: Oklahoma City, Dec. 13. Sec., Dr. James D. Osborn, Jr., 3854 Santurce.

OREGON: Basic Science. Portland, Oct. 28. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

Puerto Rico: Santurce, Sept. 5. Sec., Dr. O. Costa Mandry, Box 3854, Santurce.

TEXAS: Reciprocal Endorsements. Dallas, July 30. Sec., Dr. T. J. Crowe, 918-1920 Mercantile Bldg., Dallas.

VERMONT: Burlington, Feb. 13-15. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

VIRGINIA: Richmond, Dec. 13. Sec., Dr. J. W. Preston, 30 1/2 Franklin Road, Roanoke.

WISCONSIN: Basic Science. Madison, Sept. 23. Sec., Professor Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee.

WYOMING: Cheyenne, October. Sec., Dr. M. C. Keith, Capitol Bldg., Cheyenne.

Minnesota April Report

Dr. Julian F. Du Bois, secretary, Minnesota State Board of Medical Examiners, reports the oral, written and practical examination held at Minneapolis, April 18-20, 1939. The examination covered twelve subjects and included sixty questions. An average of 75 per cent was required to pass. Seventy-nine candidates were examined, all of whom passed. Four physicians were licensed by reciprocity and two physicians were licensed by endorsement. The following schools were represented:

PASSED

School	Year	Per Cent
Stanford University School of Medicine	(1938)	88.3
George Washington University School of Medicine	(1938)	88.3
Northwestern University Medical School	(1936)	87.4
(1937) 89.3, (1938) 84.5, 85.2, 86.6, 89.1, 89.6, 89.7, 91.5, 92.2	(1934)	92.1
Rush Medical College	(1938)	85.6, 86.1, 88.1
School of Medicine of the Division of Biological Sciences	(1937)	89.4, 90
University of Illinois College of Medicine	(1937)	90.1
Indiana University School of Medicine	(1937)	

District of Columbia Reciprocity Report

Dr. George C. Ruhland, secretary, District of Columbia Commission on Licensure, reports four physicians licensed by reciprocity, March 28, 1939. The following schools were represented:

LICENSED BY RECIPROCITY

School	Year	Reciprocity
Johns Hopkins University School of Medicine	(1934)	with Maryland
University of Maryland School of Medicine and College of Physicians and Surgeons	(1921), (1933)	Maryland Virginia

Oklahoma Reciprocity and Endorsement Report

Dr. James D. Osborn Jr., secretary, Oklahoma State Board of Medical Examiners, reports eight physicians licensed by reciprocity from Jan. 10 through May 27, 1939. The following schools were represented:

LICENSED BY RECIPROCITY

School	Year	Reciprocity
University of Arkansas School of Medicine	(1937)	with Arkansas
Rush Medical College	(1937)	Missouri
University of Illinois College of Medicine	(1937)	Illinois
Washington University School of Medicine	(1937)	Kentucky
Jefferson Medical College of Philadelphia	(1937)	Missouri
University of Texas School of Medicine	(1937)	N. Carolina
University of Wisconsin Medical School	(1937)	Texas Wisconsin

School	Year	Reciprocity
Johns Hopkins University School of Medicine	(1936)	88.2
Harvard Medical School	(1936)	88.5
University of Minnesota Medical School	(1935) 89.6, (1938) 85.6, 86.3, (1938) 82.3, 83.1, 84.3, 84.4, 85.1, 85.3, 85.5, 86.1, 86.2, 87.2, 87.6, 89.1, 91.3, 92.4, 93.1, 94.5, (1939) 83.2, 83.5, 84.2, 85.4, 85.5, 85.6, 86.3, 87.1, 87.6, 87.6, 88.2, 88.4, 88.5, 88.5, 88.6, 89, 89.4, 89.6, 93.6	89.5
Washington University School of Medicine	(1937)	89.1
Creighton University School of Medicine	(1938)	82
Cornell University Medical College	(1935)	89.6
Ohio State University School of Medicine	(1936)	88.6
Western Reserve University School of Medicine	(1936)	89.5
Hahnemann Medical College and Hospital of Philadelphia	(1938) 87.4, 88	
University of Pennsylvania School of Medicine	(1937)	86.1
University of Vermont College of Medicine	(1933)	90.5
University of Virginia Department of Medicine	(1937)	82.3
University of Wisconsin Medical School	(1937)	83
University of Manitoba Faculty of Medicine	(1938)	87.6
University of Toronto Faculty of Medicine	(1938)	88.4
McGill University Faculty of Medicine	(1916)	81.2
School	(1937)	86
Rush Medical College	(1937)	
State University of Iowa College of Medicine	(1934)	W. Virginia
Johns Hopkins University School of Medicine	(1926)	Iowa
University of Michigan Medical School	(1935)	Maryland Michigan
School	(1934)	
University of Pennsylvania School of Medicine	(1936)	N. B. M. Ex.
University of Vermont College of Medicine	(1937)	N. B. M. Ex.
*This applicant has received the M.B. degree and will receive the M.D., degree on completion of internship.		

Idaho April Examination

Mr. H. B. Whittlesey, director, Bureau of Occupational License, reports the written examination held by the Idaho State Medical Examining Board at Boise, April 3-7, 1939. The examination covered twenty-two subjects and included 160 questions. An average of 75 per cent was required to pass. Eighteen candidates were examined, eleven of whom passed and seven failed. The following schools were represented:

PASSED

School	Year	Per Cent
College of Medical Evangelists	(1938)	81

Book Notices

Everyday Surgery. By Lambert Rogers, M.Sc., F.R.C.S., F.R.C.S.E., Professor of Surgery, University of Wales, and A. L. d'Abreu, M.B., Ch.M., F.R.C.S., Senior Assistant, Surgical Unit, Welsh National School of Medicine, Wales. With an introduction by Professor G. Grey Turner, D.Ch., M.S., F.R.C.S. Cloth. Price, \$4.75. Pp. 286, with 160 illustrations. Baltimore: William Wood & Company, 1938.

In this book the authors present in concise form what they consider the best accepted opinions in modern surgical practice of an everyday as contrasted to a special character. The presentation is brief and dogmatic, focusing attention on essentials in diagnosis and treatment. Stress is laid on minor technical procedures. There is no prolonged discussion of etiology, pathology or even varieties of treatment. Entire subjects are covered frequently in one or two brief sentences. The material is decidedly accurate and is presented in clearcut manner. The book covers the entire field of general surgery with the exception of gynecology and diseases of the eye, ear, nose and throat. It will be useful to the general practitioner who is confronted with an occasional surgical problem in the management of which he may require guidance.

Die elektrischen Gruppen in Biologie und Medizin. Von Rudolf Keller. With an English summary. Paper. Pp. 92, with 9 illustrations. Zurich: Sperber-Verlag, [n. d.].

This book may be considered an introduction to a relatively new department of biologic science that may be designated as "electrocytology," which has to do with measuring the static electric charges of cells or even of portions of cells. As long as cells live they have a more or less positive electrostatic charge in relation to their surrounding fluid. This charge may be measured in the living organism by means of direct microelectrometry or by estimating in ultraviolet light the concentration in living organs of dyes with known electric charge. Thus, for instance, it has been shown that usually the parenchyma is more electropositive than the connective tissue.

To follow the revelations of electrocytology one must abandon the concept of the electric charges displayed by ions during electrolysis (resulting from high amperage and low voltage electricity) and familiarize oneself with the startling fact that, in the complex solutions surrounding the living cells, ions of identical electrolytic charge may carry opposite electrostatic charges (high voltage and low amperage electricity). Thus, while both potassium and sodium ions are electrolytically positive, in biologic mediums the potassium by becoming bound to electrostatically negative compounds such as carbohydrates assumes an electrostatically negative charge. Sodium remains electrostatically positive. In consequence the positive living cells attract the electronegative potassium, the well known dominant inorganic constituent of cells, and they repel electropositive particles such as sodium, which becomes the dominant inorganic constituent of the fluids surrounding the cells.

Potassium as a cell constituent represents an "electric group" of Keller to which sugar, urea and phosphate belong, in contrast to sodium, which is a representative of the water, chloride and amino acid group, the well known serum constituents. This separation of the constituents of the organism into two groups has been described, prior to Keller, by numerous investigators, but the reason for it has not been thus evaluated.

The rule of the "electric groups" may become of tremendous significance in our understanding of normal and pathologic biologic processes. Thus the quantitative relation between potassium and sodium in a tissue, determined by chemical assay, is one way of demonstrating the electrostatic charges in an organ. When cells become fatigued or diseased, their electric potential decreases and potassium escapes the affected parenchyma cells while sodium invades them. Hence a high sodium content of a parenchymatous organ may be considered a sign of illness.

Electrocytology enables one to comprehend better many phases of muscular and nervous action, of the permeability of capillaries, the development of edema and of cloudy swelling, the fluid metabolism of the eye and the production of lymph. It helps to explain the complex secretory and reabsorptive processes in kidney and liver, other glandular organs and the gastrointestinal tract. It promises to revolutionize our understanding of pharma-

cology and of therapeutics. The electrostatic charge of a drug when in solution in the fluids of the body and as measured by means of the high tension apparatus will help one to determine its localization in the cells or in the fluids of the body. Still more remarkable is the concept of Keller that drugs are capable of influencing the charge of diseased cells. Thus he visualizes that the positive charge of certain cells, decreased by disease, may be restored to a more nearly normal one by certain drugs with special affinities, such as aminopyrine or strophanthin. It seems not impossible that the action of cathartics and diuretics may be explained by changes in the electric charges of certain cells.

New Ways in Psychoanalysis. By Karen Horney, M.D. Cloth. Price, \$3. Pp. 313. New York: W. W. Norton & Company, Inc., 1939.

Nearly fifty years ago Sigmund Freud published the first of a series of clinical observations and formulations relative to the treatment of neurotic patients. In subsequent publications he broadened and frequently revised his views in the light of further observations. The novelty of the material and the wide departure from the accepted conceptions aroused great resistance on the part of the medical profession, but the intelligence, honesty and self criticism of the discoverer of psychoanalysis plus the therapeutic success of the method gradually won for it the respect of large numbers of medical men. Since then the growth and development of psychoanalysis have continued in a decent and orderly fashion, like those of other scientific disciplines, contributed to by hundreds of serious, scientific workers who have added their observations and made their suggestions to their colleagues for the modification of this or that detail in the theory or in the technic.

The author of the book under review was for many years associated with the main body of psychoanalysts. Recently, however, she became convinced that neither Freud nor any of the hundreds of psychoanalysts who have been working during the fifty years since Freud began have been quite right about psychoanalysis. It is almost incredible that any one should be so ambitious as to announce, as she does, that the "purpose of this book is . . . through eliminating the debatable elements, to enable psychoanalysis to develop to the height of its potentialities." For nearly half a century these debatable elements have been continually worked over and, in many instances, clarified by the rank and file of psychoanalysts. That this author should essay to straighten the matter out once and for all by her revolutionary discoveries is a confession of a lack of perspective.

The author proceeds to set up a series of propositions inferentially or directly ascribed to Freud (many of them incorrectly stated) and, having made them appear more or less absurd, she follows them with ideas which she labels her own (many of which have been standard conceptions for years past) couched in language which is intended to ring the gong of common sense. Time after time there occur such juxtapositions of the distorted theories of Freud followed by the levelheaded revisions of Horney. She refers to herself in the footnotes twenty-nine times; Freud is referred to twenty-three times and no other author more than a few times.

All this is the more regrettable because the book contains here and there some excellent points. Her compulsion to revise Freud is so insistent, however, and the commendable pages are interspersed with so much polemic that the book cannot be recommended to medical readers.

The author clearly does not expect it to be read by medical men. She accuses Freud of having a "biologic orientation," contrasting this (unfavorably) with the "social orientation," which she regards herself as having acquired. Setting biologic orientation up against social orientation is an empty, polemic trick without essential meaning, since society is made up of biologic units.

Psychoanalysis is a medical discipline. Its original technics were discovered by a physician. Its development has been largely at the hands of physicians, and its administration in this country is entirely in the hands of physicians. There is, as every one knows, a widespread tendency at the present time to accuse medicine of being antisocial or at least unsocial in its orientation. This criticism undoubtedly has had some basis in fact. Many physicians are endeavoring to correct their

astigmatism and give to the pressures and forces deriving from the social structure their proper consideration. It is unfortunate that this book, which presumably strives toward a greater clarification of the role of these social factors, should have sacrificed its value for the physician by misplaced emphases and a prevailing tone of disparagement toward some of the principles and personalities of psychoanalytic medical science.

Über exogene Reinfekte und die Superinfektion bei Tuberkulose. Von Dr. Franz Ickert, Oberregierungs- und Obermedizinalrat in Stettin. Nr. 71, Tuberkulose-Bibliothek, Beihefte zur Zeitschrift für Tuberkulose. Herausgegeben von Dr. Franz Redeker, Oberregierungs- u. Obermedizinalrat, Berlin, und Dr. Karl Diehl, dirigierender Arzt, Sommerfeld. Paper. Price, 9 marks. Pp. 67, with 47 illustrations. Leipzig: Johann Ambrosius Barth, 1939.

In this report the author devotes a good deal of space to exogenous reinfection. He refers to the teachings of Romer and numerous other authors who have worked on this subject. Cases are cited to show that such reinfection occurs. A great deal of the remainder of the study is devoted to superinfections, referring to the work of Lange and calling attention to such subjects as the exogenous stimulation of the endogenous reinfection. One hundred and seventeen references are cited on the subject of exogenous reinfection and superinfection in tuberculosis.

Die Grundlagen der neuzeitlichen Ernährung des deutschen Menschen: Ein Leitfaden für Studierende und Ärzte. Von Dozent Dr. Ferdinand Bertram, leitender Arzt der zweiten medizinischen Abteilung des Allgemeinen Krankenhauses Barmbeck, Hamburg. Boards. Price, 5.80 marks. Pp. 140, with 6 illustrations. Leipzig: Georg Thieme, 1939.

This volume is an introductory textbook in German for students and physicians. It takes up the general question of nutritional requirements, with tables of protein requirements and other essentials and the functions of the vitamins and minerals. The first part concerns the physiologic basis of nutrition. There is in the second part a discussion of foods from the standpoint of recent knowledge of nutrition, public health and agriculture. The third part discusses the food of healthy persons and provides an outline of suggested meals for Germans; the fourth part, foods, vegetarianism and fasting, and the fifth part, the nutrition of the sick. The book contains a list of references and a suitable index.

The American Way of Life. By George E. Sokolsky. With an introduction by Fulton Oursler. Second edition. Cloth. Price, \$2. Pp. 180. New York & Toronto: Farrar & Rinehart, Inc., 1939.

This book is made up largely of articles prepared at the request of Fulton Oursler of *Liberty*, whose daughter returned from school one day and asked him why his magazine contained advertising, since it was misleading, created a demand for products that were not needed or wanted and was an economic waste, increasing the purchase price. She had been taught these precepts in school in a reading from a "guinea pig" book. This book is essentially a defense of advertising and an answer to all "guinea pig" books, designed to counteract their effect in destroying confidence in business and its advertisements. The author points out that the American standard of living is far above that of any other nation, even during a depression. He does not go into the question of relief of unemployment or concern himself with persons having an inadequate income for the necessities of life, and it is reasonable to presume therefore that a marxian theorist would consider the entire book so much folderol. To an unprejudiced reader, however, there is something to be said for the author's point of view. It cannot be denied that he has described certain features of the American way of life, but it can be reasonably questioned whether his defense of advertising and business is always fair and just. The principal plea of the author is that advertising reduces rather than increases the cost of consumer goods, and this by virtue of the fact that distribution and sales on a sufficiently large scale to reduce the cost per unit are possible only through advertising. His story of the creation of the demand for the orange and its development into an essential of the American dietary, with its production a major American enterprise, is a reasonable answer to those critics of advertising who claim that if there was any need for a product its sale would be as extensive without advertising as with it. He defends the right of the American to purchase what he wants when he wants it, regardless of

whether it is a necessity or a less useful item, and describes the development of certain great business through the medium of advertising as being possible only because of this right. He calls attention to the number of people gainfully employed in such industries, which could not exist without advertising. While he resorts at times to exaggeration and is somewhat inaccurate, he is not as guilty in these respects as the authors of the books he is condemning. His tabulation of the creeds of advertisers and business associations is interesting, and yet these creeds remind the reviewer of a media representative, who lauded a code of self reform which was actually a program for avoiding much controversy with the Federal Trade Commission act under the stipulations of the Wheeler-Lea amendment. The author pleads that all advertising should not be criticized on the basis of black sheep advertising and praises the attempts of advertising people and big business to reform themselves, but he fails to mention that it took storms of protest, rather than internal reform, to create a public consciousness that demanded the enactment of the new Food, Drug and Cosmetic Act and the Wheeler-Lea amendment. On several occasions the author mentions the American Medical Association, and he is reasonably fair in his reference to it. Some of the comparisons which he makes between the doctor's prescription and the "patent medicine" are not justified, but, since he is not a physician, he might not be expected to write authoritatively on that subject. The reviewer does not agree with the publisher that the author has not "whitewashed," nor does he agree that he has given a true description or described the real significance of the "black sheep" in the advertising field. He states that there must be nothing fraudulent in advertising and that the public is protected against such things by legislation, but he fails to note that frauds are rampant, that the effect of the new legislation is just becoming apparent and that it will be many years before its full effectiveness is felt. The book makes pleasant reading, the author's enthusiasm is refreshing if not always accurate, and his analyses of advertising are interesting if not always complete.

Fürsorgerische Beobachtungen über die Anfänge der Lungentuberkulose des Erwachsenen. Von Prof. Dr. J. E. Kayser-Petersen, Leit. Arzt der Tuberkulosefürsorgestelle an der Med. Univ.-Poliklinik Jena, und Dr. K. H. Grenzer. Tuberkulose-Bibliothek, Beihefte zur Zeitschrift für Tuberkulose, Nr. 70. Herausgegeben von Dr. Franz Redeker, Oberregierungs- u. Obermedizinalrat, Berlin, und Dr. Karl Diehl, dirigierender Arzt, Sommerfeld. Paper. Price, 15 marks. Pp. 90, with 86 illustrations. Leipzig: Johann Ambrosius Barth, 1939.

The cases reported are divided into various groups, in the first of which there were early pulmonary infiltrations. Numerous illustrations, all from roentgenograms of the chest, show various steps in the development of these infiltrations in different locations. In another group pulmonary tuberculosis followed pleurisy with effusion, while in still another the tuberculous lesions developed in the region of the hilus of the lung. This work has been carefully done and the report contains valuable information.

Trudi konferentsii po medichnii biologii (Kiev, 15-19. XI. 1936). [Studies of the Conference on Medical Biology Held in Kiev, Nov. 15-19, 1936.] Paper. Price, 12 rubles, 50 kopecks. Pp. 304, with illustrations. Kiev: Vydavnistvo Akademii Nauk URSR, 1937.

This volume contains papers read at the Conference on Medical Biology held in Kiev Nov. 15-19, 1936, in order to bring together workers in the various research institutions devoted to biology, to establish closer relations between biologists and medical men and to discuss the teaching of biology in medical schools. The thirty-five papers presented are in the Ukrainian and Russian. They deal chiefly with problems in evolutionary physiology, dynamics of growth and medical parasitology.

The Diabetic A B C: A Practical Book for Patients and Nurses. By R. D. Lawrence, M.A., M.D., F.R.C.P., Physician in Charge Diabetic Department, King's College Hospital, London. Sixth edition. Boards. Price, 3s. 6d. Pp. 64. London: H. K. Lewis & Co., Ltd., 1939.

This little volume is written for patients, to acquaint them with the general problem of diabetes and its treatment. It is a practical manual which tends to give the patient an intelligent comprehension of the medical as well as dietary phases of the subject. He is told the things which concern him and his daily routine, and each important point is emphasized. A considerable part of the book is devoted to diet and recipes. In this

Lawrence uses good judgment throughout and tries so hard to make the burden easy that one almost thinks that he himself is diabetic. He uses the English system of weights and measures, interspersed with the metric system, which to an American audience would be slightly confusing. The book is written much along the general lines of all diabetic manuals and is clear and concise.

Études radiographiques du poumon tuberculeux: Interprétation de radiographies pulmonaires. Par Jacques Stéphan, privat-docent de médecine interne à la Faculté de médecine de Genève. Paper. Price, 45 francs. Pp. 138, with 205 illustrations. Paris: Amédée Legrand, 1939.

In this fine volume the author begins with the x-ray appearance of the normal chest and proceeds to the smallest changes from the normal that can be detected on the x-ray film. He places considerable emphasis on blood vessels and the possibilities of misinterpretation of shadows cast by them. From the early changes he proceeds to most extensive disease, and he places especial emphasis on cavitation in all its phases of development.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Arthritis in Relation to Trauma and Pre-Existing Osteomyelitis.—The claimant, who previously had had osteomyelitis in the region of the right thigh and left knee, in the course of his employment as a hooker in connection with skidding logs, was struck just below the left knee by a catapulting small tree. He instantly suffered severe pain and limped but was able to continue work until ten days thereafter. He continued to have pain in the region of the left knee joint and that area became swollen. Eight days after the accident he went to his employer's contract physician, who had previously treated him for osteomyelitis, and requested medical treatment but was refused such treatment because the physician considered his condition to have been caused by the pre-existing osteomyelitis rather than by any accident. Thereafter, the claimant secured medical and surgical treatment and hospitalization through another physician. Multiple abscesses developed in the region of the left knee necessitating numerous surgical incisions to establish drainage. His left knee joint was aspirated on three occasions and pus obtained which, as shown by laboratory examination, contained pneumococci. A subluxation of the left tibia at the knee joint developed which the attending physician endeavored to reduce under spinal anesthesia. Thereafter five different plaster casts were applied to his leg. His left knee joint became ankylosed and draining sinuses persisted in the region of that joint. The claimant brought proceedings under the workmen's compensation act against his employer and his employer's insurance carrier. From an order of the industrial accident board awarding compensation and expenses for medical and surgical treatment and hospitalization, the employer and his insurance carrier appealed to the Supreme Court of Idaho.

At the hearing before the industrial accident board three expert medical witnesses, who had not seen the claimant at the time of or immediately after the accident but had previously treated him for osteomyelitis, testified that the claimant's condition following the accident was the result of the pre-existing osteomyelitis and not of the injury. The physician who treated the claimant after the accident testified that the claimant's condition, an "acute suppurative traumatic arthritis of the left knee" due to a pneumococcal infection, had been caused by trauma. It was his opinion, based on roentgenograms and physical examinations, that the bone marrow had not become infected, as would have occurred if osteomyelitis had been present; that the infection started in the knee joint and remained there for possibly three weeks before any bone involvement was demonstrable by roentgen examination, and that when the bone finally became infected it was an extension from the infection in the knee joint. He further testified that the "pneumococcus

isn't a very common infection for either osteomyelitis or a joint," but if pneumococci settle in an injured area they may set up an infection and cause such a condition as was found in the claimant. In the judgment of the Supreme Court, the testimony in support of the board's award in favor of the claimant was positive and of more weight than the negative testimony to the contrary adduced by his employer and his employer's insurance carrier. Accordingly, the court affirmed the order of the board, awarding compensation and reimbursing the claimant for the expenses incurred by him in obtaining medical and surgical treatment and hospitalization.—*Arneson v. Robinson (Idaho)*, 82 P. (2d) 249.

Narcotics: Issuance of Narcotic Prescription in Name of Fictitious Person.—The narcotic law of the state of Washington provides that "any person who shall falsely make, forge or alter or knowing the same to have been falsely made, forged or altered shall present to any druggist a physician's prescription with intent by means thereof to procure from such druggist any narcotic drug as defined in this act shall be guilty of a felony. . . ." A physician, said the Supreme Court of Washington, who issues a narcotic prescription in the name of a fictitious person and delivers it to a person not named, knowing and intending that the person to whom it is given will, by a fictitious endorsement, procure narcotic drugs from a druggist, violates the narcotic law of this state by falsely making a narcotic prescription. Furthermore, any person who knowing a physician's prescription to have been falsely made presents it to a druggist with intent to procure a narcotic drug also violates that law.—*State v. Harkness et al. (Wash.)*, 82 P. (2d) 541.

Motor Vehicles: "Under the Influence of Intoxicating Liquor" Defined.—A New Mexico statute prohibits any person from operating a motor vehicle in that state while "under the influence of intoxicating liquor or narcotic drugs." In the opinion of the Supreme Court of New Mexico, a person who has taken a drink of intoxicating liquor is not necessarily under its influence but is under its influence if the drinking of intoxicating liquor affects him so that, even to the slightest degree, he is, as was stated by the Supreme Court of Arizona in construing a similar statute in *Hasten v. State*, 35 Ariz. 427, 280 P. 670, "less able, either mentally or physically or both, to exercise the clear judgment and steady hand necessary to handle as powerful and dangerous a mechanism as a modern automobile with safety to himself and the public." The court concluded that the testimony in the present case to the effect that the defendant's breath smelled of whisky at the time of the accident and that he was nervous and restless immediately after the accident was insufficient to prove that he was under the influence of intoxicating liquor.—*State v. Sisneros (N. M.)*, 82 P. (2d) 274.

Wyoming State Medical Society, Salt Lake City, Utah, Sept. 5-7. Dr. M. C. Keith, 156 South Center St., Casper, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Nonconvulsive Pregnancy Toxemias: Their Relationship to Chronic Vascular and Renal Disease. D. E. Reid and H. M. Teel, Boston.—p. 886.

Eclampsia and Vascular Renal Disease.—In trying to determine what percentage of eclamptic or preeclamptic patients are likely to have permanent vascular renal damage, a recurrence of the toxemia, a subsequent normal pregnancy, to abort, have an abruptio placentae, a stillborn fetus and the like, Dieckmann and Brown studied their own data obtained from pregnancies following toxemia and that of more than 115 papers dealing with the follow-up of patients who have had toxemia of pregnancy. They especially selected reports of cases in which a subsequent pregnancy had occurred after toxemia, because it is generally agreed that pregnancy is the best test of the vascular renal system. Their conclusions are that subsequent pregnancies will be normal in 40 per cent of the cases of eclampsia and complicated by a recurrence or exacerbation of the hypertension, edema or albuminuria in 40 per cent. Less

than 10 per cent will have a recurrence of the eclampsia. More than 37 per cent of the patients had vascular renal disease, indicated usually by a hypertension. The authors found no evidence of chronic glomerulonephritis in any of their eclamptic patients. In nonconvulsive toxemia of pregnancy subsequent pregnancies will be normal in at least 30 per cent and probably 40 per cent of the cases and complicated by a recurrence or exacerbation of the hypertension, edema or albuminuria in from 50 to 70 per cent. More than 40 per cent of the patients had vascular renal disease, evidenced usually by a hypertension. Renal impairment, as indicated by a urea clearance of less than 50 per cent and due to nephrosclerosis, occurred in 2 per cent. Chronic glomerulonephritis was present in 0.5 per cent. The authors believe that true eclampsia and preeclampsia do not cause permanent vascular or renal damage and that, when such damage occurs, either the condition was not eclampsia or preeclampsia or these diseases were superimposed on a patient with a predisposition to hypertensive arterial disease. The fetal mortality, including all fetal deaths from abortion, stillbirth and neonatal deaths, is more than 25 per cent in all pregnancies after eclampsia and 15 per cent after nonconvulsive toxemia. In toxemic pregnancy after eclampsia it is more than 40 per cent and in recurrent toxemia it is more than 20 per cent. Normal pregnancies after eclampsia or preeclampsia have a 5 per cent fetal mortality. Eclampsia and preeclampsia rarely occur without premonitory signs of excessive or too rapid gain in weight, edema, abnormal increase in blood pressure, hypertension or proteinuria. Either disease may recur, but such a repetition should always suggest vascular renal disease.

Endometriosis.—Counseller states that, regardless of their particular location, the lesions of endometriosis have as their common denominator the presence of endometrial tissue which is indistinguishable pathologically and physiologically from that found within the uterine cavity. The lesions are neither tumors nor products of inflammation, although they have some of the characteristics of both pathologic phenomena. Endometriosis appears to be associated frequently with primary or secondary sterility and in a large proportion of cases there is associated disease of the uterus or adnexa. In many cases in which this condition is found, an abdominal or a pelvic operation has been performed previously. At the Mayo Clinic an incidence of pregnancy of only 56.5 per cent was found; previous surgical procedures had been carried out in 54.2 per cent of cases and associated disease of the uterus or ovaries or both was found in more than 50 per cent. Aberrant endometrium may appear within the uterus, in the pelvic tissues or organs and finally in locations which are distant from the uterus. In all of these locations the pathologic changes are identical; there are glandular tubules identical with the epithelial diverticula of the uterine mucosa, formed of simple columnar epithelium which is often ciliated. Around these epithelial formations there is a connective tissue containing nuclei, resembling that in the subendometrial tissue of the uterus. In addition to this morphologic resemblance the endometrial formation, under the influence of the ovarian hormones, follows the menstrual cycle of the uterus; hemorrhage occurs, cysts form and rupture may ensue. During pregnancy the ectopic tissue undergoes formation of decidua, involution occurring subsequently. The author reviews the embryonic metaplastic and migratory hypotheses which purport to explain the pathogenesis of endometriosis and states that from the manner of the distribution of the implants the hypothesis that endometrial tissue from the uterus is carried by lymph channels to points outside the uterus is the least objectionable. Pelvic pain, quite definitely related to menstruation, is the principal complaint for which the patient seeks relief. There is usually a ten year history from the onset of the disease and the symptoms have been progressive. Either radical or conservative surgical intervention, depending on the extent and involvement of the lesions, is indicated.

Endocrine Therapy in Artificial Menopause.—Schneider epitomizes the conclusions and observations derived from the study of 434 cases of artificial or physiologic menopause. Any combination of symptoms of the syndrome occurring prior to, during or after the so-called menopause must be given consideration as evidence of estrogenic deficiency. Therapeutic results may be more promptly and effectively obtained by accurate

determination of therapeutic requirements, which vary in each instance. Early institution of endocrine therapy results in more prompt and effective response (relief of symptoms in 281 of 331 premenopausal patients) with smaller dosages than late or delayed therapy (relief obtained by ninety-nine of 103 menopausal cases) with large doses. While parenteral therapy is most effective for the determination of therapeutic requirements, oral therapy provides a more satisfactory and sustained effect. Prophylactic estrogenic therapy in artificially induced menopause is suggested. Although the method has been utilized early in only twenty-one cases of artificially induced menopause, the significance of the results would seem to be considerably enhanced by the rather similar results of the entire series.

Condition Simulating Tabes Dorsalis.—Bailey and Saskin discuss the occasional innocence of pupillotonia with absent tendon reflexes. In August 1937 a man of 25 of sound mind and body consulted them because he had repeatedly been refused life insurance on the ground that he exhibited metasyphilitic manifestations. He had large pupils that were immobile to light but reacted to accommodation-convergence; in addition, his ankle and knee jerks were absent. His sister, aged 24 years, in sound health and well poised, presented a similar clinical picture. Adie's statement that pupillotonia is a disease *sui generis* is disputed by those who contend that cases of pupillotonia should be divided into two distinct groups: (1) pupillotonia appearing as the sole clinical manifestation in a healthy individual and (2) pupillotonia as part of a general morbid state. It is to the first group that the eponym "Adie's syndrome" may be applied appropriately.

Mediastinal Glandular Tuberculosis.—Pfahler discusses a case of mediastinal glandular tuberculosis of the primary childhood type occurring in a man of 30. A diagnosis of Hodgkin's disease was made repeatedly by various competent roentgenolo-

gists and internists in different parts of the world. The author states that the case illustrates the difficulty and importance of considering tuberculosis in every case of mediastinal Hodgkin's disease or lymphosarcoma. When there is associated enlargement externally of the lymphatic glands, it would seem advisable to avoid delay by removal of a gland early in the diagnostic procedures. This may be done more safely after preliminary irradiation, especially when lymphosarcoma is suspected. Differentiation may have to depend on the degree of radiosensitivity of the mediastinal tumor. The radiosensitivity would probably range progressively from Hodgkin's disease, lymphatic leukemia and lymphosarcoma to tuberculous lymphoma.

Diagnosis of Idiopathic Steatorrhea.—From a study of the x-ray signs in six cases of idiopathic steatorrhea, Kantor points out that the characteristics in the small intestine are the "moulage sign," dilatation and segmentation; in the colon dilatation and redundancy; in the gallbladder a faint filling, and in the bony skeleton osteoporosis, deformity and dwarfism. These signs are not all present in every case but vary in their degree and distribution depending on the activity of the disease and the constitution of the individual. The changes in the small intestine are most apparent in the jejunum. These consist of variations in tone, caliber and motility and particularly in the diminution or complete disappearance of the distinctive valvulae conniventes. The term "moulage sign" calls attention to the striking appearance of the upper jejunum when the valvulae conniventes are missing and the lumen is filled smoothly as though wax had been poured into it. Since this peculiar appearance seems to vary directly with the intensity of the steatorrhea, the sign may have practical value in both diagnosis and prognosis. Idiopathic steatorrhea is probably the only form of grave chronic diarrhea in which the colon is dilated instead of contracted.

Amphetamine Sulfate in Behavior Problems.—Cutts and Jasper believe that their study of twelve behavior problem children with abnormal electro-encephalograms clarifies the disorder in a specific group of children who have been called epileptoid because of personality characteristics and electro-encephalograms similar to those of epileptic patients. In about half the cases in this group there appears to be a more specific disorder, identified by a favorable response to amphetamine and the presence of a prominent six cycle rhythm in the electro-encephalogram. This group of cases probably represents the same disorder in children as that described as "psychomotor epilepsy" in adults, in whom it was found that phenobarbital tends to increase rather than to decrease the number and

severity of the attacks. The changes in personality with amphetamine are probably due to an alteration in the patient's emotional reactions to the type of brain disorder revealed in the electro-encephalogram without any fundamental change in the disorder itself. Since the brain potentials recorded through the skull are chiefly of cortical origin, the amphetamine may act on subcortical centers which are not closely related to the type of cortical function shown in the electro-encephalogram. This may be suspected from the fact that benzedrine is known to affect particularly the autonomic nervous system. As practically nothing is known at present regarding the cause or origin of the six cycle rhythm, which seems to be the main abnormality in these patients, the authors think that further speculation is not justified at present.

Asphyxia and Drowning.—Loughheed and his colleagues report further studies on experimental drowning and asphyxia. Their preliminary study was abstracted in THE JOURNAL Oct. 15, 1938, page 1505. From their present experiments they recommend certain resuscitative measures as a basis for the treatment of apparently drowned persons. The same measures may be of value in the treatment of patients suffering from other acute asphyxial conditions. All foreign matter should be removed from the mouth, larynx and pharynx. In the cases of drowning the body should be gently lifted up by the waist, to allow as much water as possible to drain from the stomach and lungs. The body should then be placed in the prone position with the head and chest lower than the rest of the body if at all possible. With the head of the patient slightly retracted and lying on one side, the Schafer method of artificial

respiration should be started at once. There should be a free passage of air into and out of the chest. To facilitate this the tongue should be pulled forward, and if the passage of air cannot be heard the introduction of a tracheal catheter is almost essential. When the catheter has been passed, initial suction on this tube should remove much of the foam filling the trachea and bronchi. Since insufflation of the lungs with 5 per cent carbon dioxide and 95 per cent oxygen is valuable in artificial respiration in experimental asphyxia, the procedure might be used to advantage in cases of drowning. The gas mixture can be passed into the lungs through the tracheal catheter, the excess air on forced expiration readily escaping through the glottis around the catheter. If special apparatus is not to be had, a pearl of amyl nitrite may be crushed and held over the open end of the tracheal catheter during the inspiratory phase of the artificial respiration. After two or three whiffs of this the administration of the carbon dioxide-oxygen mixture is recommenced at a rate of about 3 liters per minute. Prompt, adequate and prolonged artificial respiration is the fundamental treatment for drowned, asphyxiated or electrocuted persons.

Overtreatment in Syphilis.—During the last few years Cormia encountered five instances of well defined overtreatment in patients receiving combined neoarsphenamine and preparations of bismuth. The gradual development and insidious nature of the symptom complex make it particularly susceptible to misinterpretation, and many patients have been precipitated into actual mental or physical breakdown by the persistence of misguided therapeutic measures. Three patients illustrating this syndrome complained of nervous irritability. It was evinced as an exaggerated response to external stimuli, uncontrollable temper, general emotional instability, minor lapses of memory and a persistent insomnia. Diffuse, throbbing headaches, a not infrequent manifestation of bismuth intolerance, were consistently present. The depressing influence of the bismuth therapy was clearly shown by the general symptoms of fatigue, weakness and loss of weight. All the patients were physically below par and complained of persistent malaise even while resting from their regular occupations. Since this depressing effect is rarely observed when bismuth compounds alone are given, it is reasonable to assume that it is due to the prolonged administration of both arsenic and bismuth compounds. In the fifth patient and to a lesser degree in the fourth one the arsenical factor in therapy, resulting in a toxic hepatitis, was in a large measure responsible for the general depressing effects. Loss of appetite, a varying degree of chronic dyspepsia and constipation were present in all five patients. In the last two patients this was in part referable to specific hepatic damage from arsenic, but in the remainder such involvement, if present was subclinical. Nervous system hyperirritability, with sympathetic reflex changes, could not be eliminated as a factor in the gastrointestinal stasis. There was no definite evidence of spasticity in the one patient in whom a barium sulfate study of the gastrointestinal tract was made. Three of the five patients were distressed by a chronic nonproductive cough. This occurred in the absence of any signs of chronic bronchitis and aneurysmal pressure. Chronic cough may possibly represent a combined action of both arsenic and bismuth or to some degree a secondary mild infection dependent on lowered general resistance. The fourth patient suffered from a chronic dermatitis which was undoubtedly precipitated by the prolonged administration of bismuth compounds. The previous excellent general health and splendid physique of this patient may have been a factor in the absence of other cumulative effects from the prolonged antisyphilitic treatment. It should be recalled that the arsphenamines, when given in short courses and in relatively small dosage, have a well recognized tonic and non-specific stimulating effect. When large doses are given over prolonged periods the reverse is true and the effect is one of chronic depression. Nervous irritability is undoubtedly an integral part of this depressive or cumulative toxic action.

Lead Poisoning from "Canned Heat."—Wilcox saw six cases of severe poisoning among alcoholic addicts who made a practice of drinking "canned heat." Two of the patients have drunk this for more than twenty years. On investigating the authors found that no bad effects accrued from the original fractions of the mixture. The danger seemed to lie in the

contamination of the contents by lead going into solution from the containers. Four of the six patients presented a picture of lead encephalopathy. Three of them died. The other patient made an excellent recovery from a severe encephalopathy without deleading measures or adherence to a special diet.

Vitamin B₁ in Alcoholic Polyneuritis.—McGee states that in a group of twenty-five patients with alcoholic polyneuritis treated by subcutaneous hypodermic injection of vitamin B₁ (thiamin chloride) and a control group of twenty-three patients receiving only the vitamin B₁ contained in the diet there was practically no difference in the time required for complete alleviation of symptoms. The severity of the symptoms and the time required for recovery seem to be directly proportional to the duration of the neuritis. Of the severe cases subjective relief was obtained in the group treated with vitamin B₁ in an average of 10.4 days and in the control group in eighteen days. In the moderately severe cases in the treated group complete relief of all symptoms was obtained in an average of 6.1 days and in the control group in 6.5 days. In the mild cases in the treated group complete relief occurred in an average of 4.3 days and in the control group in 4.5 days. There were no cases in either group that failed to show improvement.

Gastrointestinal Allergy.—Ehrenfeld and his associates studied seventy-five persons with proved peptic ulcer for evidences of allergic manifestations and seventy-two definitely allergic individuals for the presence of ulcer. Eight of the persons with proved peptic ulcer were found to be allergic. Four of the definitely allergic patients had peptic ulcers. This is well within the incidence of peptic ulcer for the general population. It is concluded that allergy is not a significant factor of peptic ulcer and that peptic ulcer is not of increased frequency in allergy. Nineteen allergic patients presented symptoms which could be mistaken for that of an ulcer syndrome. On repeated x-ray studies of the stomach and duodenum, eight of these showed transient spastic phenomena without a demonstrable

niche. Gray has described an ulcer-like complex as a result of an autonomic mechanism initiated by tobacco smoking or a focus of irritation, such as chronic appendicitis or renal calculi. The data suggest that an allergic process can explain the occurrence of a clinical entity closely resembling an ulcer. Among the seventy-two allergic subjects there were eight cases of urticaria or angioneurotic edema, half of these showed spastic changes in the stomach and duodenum. A fifth patient of the urticaria group had a duodenal ulcer. This lends support to the explanation of Demel that gastrointestinal allergy is due to an angioneurotic edema-like reaction and that the localized spasm demonstrated in the roentgenogram may be due to, or associated with, the presence of a wheal.

Vaccination Against Typhus Fever.—Veintemillas finds that the formaldehyde-killed suspensions of Mexican rickettsiae prepared according to the methods of Zinsser and Castaneda have evident protective power against typhus infection, as proved by experiments in men and laboratory animals. Twelve persons who had not had a previous typhus infection were vaccinated and subsequently inoculated with large doses of typhus material obtained from infected guinea pigs and in none of them did the disease develop. It was found necessary to inject at least three doses of vaccine in order to protect guinea pigs against nonorchitic Mexican strains, whereas it was easy to immunize these animals with a single dose of vaccine against the orchitic typhus. The apparent immunologic differences between orchitic and nonorchitic Mexican strains are the same as those observed between murine and European typhus.

Skin-Sensitizing Antibodies.—Winkenwerder and his colleagues show that precipitating and complement fixing antibodies to short ragweed pollen can be regularly produced in rabbits by intra-abdominal, subcutaneous, intravenous or intracutaneous injections of the pollen extract. Sixteen of twenty-nine of these antisera produced in rabbits by the injection of various extracts of short ragweed pollen contained specific ragweed skin sensitizing antibodies passively transferable to man. There was no regular correlation between the precipitin content of the serum and its ability to sensitize the human skin. Defatting the pollen or grinding it in a ball-mill had no apparent effect on its ability to excite the production of skin sensitizing antibodies. Although there was some indication that antisera of animals injected intravenously may contain less of this antibody than those injected subcutaneously or intra-abdominally, further work will be necessary to establish this point.

Passive Sensitization of Human Skin.—According to Sherman and his co-workers, six of twelve serums from guinea pigs sensitized from two to four months previously by a single injection of alum-precipitated pollen-extracts passively sensitized normal human skin. In no case was the intensity of the reac-

tion as great as that produced by serums of acutely sensitive human beings. None of the serums of animals bled less than two months after a similar injection passively transferred sensitivity to human skin. Precipitins could be demonstrated in only one of these serums. Of two anti-horse rabbit serums, both containing precipitins in high titer, one passively sensitized human skin to horse serum while the other did not. The passive sensitivity of skin was shown to be specific, both by testing with other antigens and by neutralization with the homologous antigen.

- Vascular Birthmarks: Diagnosis and Treatment. F. Young, Rochester, N. Y.—p. 671.

Physical Strength of Adolescent Girls.—Pryor and Smith measured the physical strength of 100 adolescent girls every six months for a period of seven years, that is from 10 to 17 years of age. Right and left hand grip were averaged with pushing and pulling scores and plotted against age. Strength increased with age for the total group from 10 to 15½ years, after which the curve flattened. When curves for strength tests were plotted in three groups according to body build, a marked difference was demonstrated between broad and slender girls. Broad girls were shown to possess consistently superior physical capacity by this standard when compared to slender girls through the adolescent period. Broad and slender body builds appeared to represent definite and distinct endocrine patterns.

Heredity in Stuttering.—Nelson compared the lineage histories of 204 stutterers with those of 204 nonstutterers. The subjects of both groups were matched in age and sex. Those belonging to the stuttering group were selected only because they stuttered; those belonging to the control group were selected because they spoke normally and had no history of stuttering. Additional information was secured from grandparents, aunts, uncles and friends. The trend of the data seems definitely to indicate that there must be some biologic tendency to stutter. The conclusions pointing to that tendency are as follows: A greater percentage of stutterers who have ancestral pedigrees of stuttering began to stutter when they were learning to speak, while a greater percentage of the stutterers whose pedigrees show no ancestral stuttering began to stutter after the onset of speech. There is a constant ratio in favor of the greater incidence of diseases and other precipitating factors occurring at the incidence of stuttering among stutterers whose pedigrees show no ancestral stuttering than among stutterers whose pedigrees show ancestral stuttering. Many of the stutterers with pedigrees of ancestral stuttering show a history of no diseases or other precipitating factors coincident with the onset of speech and stuttering, as compared with the percentage of stutterers with pedigrees with no ancestral stuttering. The manner and character of the accidents, frights and diseases are more violent and more severe among those stutterers having pedigrees of no stuttering than among stutterers showing stuttering in their ancestry.

Prophylaxis for Scarlet Fever Complications.—Hamilton and Togasaki believe that pooled human convalescent serum offers an entirely safe and highly effective method of treating scarlet fever and also that it is of great value in reducing the

incidence of complications. Sulfanilamide, though of little or no value in the disease itself, offers comparable protection from complications with little risk. Because of its cheapness and availability they think it may become important in the therapy of scarlet fever. The authors state that they will report later on the value of the two methods in combination.

Meningococcic Meningitis.—Campbell gives the essential features of the twenty-seven interepidemic cases of meningococcic meningitis admitted to the Walter Reed General Hospital from October 1935 to November 1938. The treatment given the twenty-seven cases consisted of antimeningococcus serum, antitoxin and sulfanilamide. Serum was administered intravenously and intraspinally immediately after the necessary sensitivity tests had been performed. Soon after the first spinal drainage, 100 cc. of serum diluted with 200 or 300 cc. of physiologic solution of sodium chloride was given slowly intravenously. The average amount of serum given in this manner to twenty-two patients was 221 cc., with extremes of 45 and 705 cc. Intraspinal serum was given warmed, undiluted, by the gravity method and in amounts of from 5 to 10 cc. less than the quantity of spinal fluid withdrawn. Intrathecal serum was given to eighteen patients in an average total amount of 106 cc., with extremes of 15 and 340 cc. Antitoxin was given to three patients before they were admitted to the hospital. Sulfanilamide was administered to seven patients in an average total dose of 32.5 Gm., with extremes of 9 and 60 Gm. Five were given both serum and sulfanilamide, while two were given sulfanilamide alone. One of the former group died after receiving 14.5 Gm. of sulfanilamide and 100 cc. of serum. A subarachnoid block developed. Sulfanilamide is best employed by mouth if the patient is not vomiting. Otherwise it can be given subcutaneously as outlined by Schwenkter. There were thirty-six complications in the entire series, including deafness, transient sixth and seventh nerve paralyzes, arthritis, optic neuritis, paraplegia, endocarditis, subarachnoid block and panophthalmitis. Five deaths occurred, two from acute fulminating meningococcemia and one from status thymicolymphaticus. The author believes that the most effective form of treatment was intravenous and intraspinal antimeningococcus serum in conjunction with oral and/or subcutaneous sulfanilamide.

Bone Changes in Primary Hypogonadism.—The changes considered to be characteristic of primary prepuberal hypogonadism are listed by Hurxthal and Hare in the order of their importance: (1) a tendency to longer bone growth, (2) delayed epiphyseal closure, (3) subcalcification, (4) thinning of

the cortical layer, (5) thin-walled, normal-sized trabeculation and (6) roughening of the metaphysial margin of growing bone. It is likely that these changes may not be present in later decades of life, as there is evidence in most cases of some gonad secretion, which, over a long period, brings about closure of the epiphyses. These changes may be differentiated from endocrine osseous changes seen in pituitary acromegaly and gigantism, prepuberal myxedema and prepuberal pituitary dwarfism or infantilism. Seven cases of typical primary prepuberal hypogonadism are presented and by way of comparison two cases of postpuberal hypogonadism in young women are cited.

Joint Changes in Hemophilia.—Newcomer maintains that the fact that characteristic changes in the joint occur in at least 80 per cent of hemophilic patients is not generally recognized by the medical profession. There are really two stages: (1) acute hemorrhage into the joint and (2) the chronic stage, in which changes in the joint are produced by these hemorrhages. Hemophilia as a causative agent in both acute and chronic disease of the joints should be carefully considered. The author reports three cases in which surgeons have repeatedly suggested or attempted operations, not realizing that the joint changes were due to hemophilia. Quite often these changes are diagnosed as due to tuberculosis or arthritis and may even go to operation before it is discovered that the patient has hemophilia. Even when the patient is known to have hemophilia, the physician may not realize that the articular condition is due to hemorrhages into the joint but may think it is due to some infection and advise removal of the teeth, tonsils and the like. Failure to diagnose such a case may be fatal to the patient. Contractions of the arm and wrist, from hemorrhage into the muscles, have been reported. One of the author's patients had this condition in both the forearm and the wrist. Hemorrhages into the hip are reported as uncommon, but Thomas reports them in 16 per cent of his cases. In two of the present three cases there were hemorrhages into the hip. Both patients were adults, but no changes are shown in the roentgenograms. When such hemorrhages occur before maturity, they produce changes resembling Perthes' disease.

Surgical Approach to Hypertension: Division V. F. M. Findlay, San Diego, Calif.—p. 277.

Congenital Factors in Thyroid Disease.—Patterson states that the various types of goiter have been produced in experimental animals by varying the iodine intake and the physiologic requirements of the gland. Hypothyroidism and hyperthyroidism likewise have been produced. The experiments suggest that, when hypothyroidism is present in the mother, she will absorb thyroxine from her fetus for her own use, leaving the fetus hypometabolic. The fetal thyroid in turn reacts by hyperplasia to produce sufficient thyroxine for its own metabolism. Therefore he believes that there are two major etiologic factors in the production of congenital goiter: (1) an iodine deficiency and (2) fetal thyroid hyperplasia caused by maternal absorption of fetal thyroxine. Damage to the thyroid before birth lays the foundation for the development of goiter later in life, depending on iodine ingestion and physiologic requirements.

Treatment of Surgical Tuberculosis in Adults. M. Forrester-Brown.—p. 107.

Tuberculosis Following Pleurisy.—Schneider believes that acute pleurisy with effusion uncomplicated by pulmonary lesions should be considered of tuberculous origin in nearly every case, and, like pulmonary tuberculosis, the majority of these cases occur in youth and early maturity. In a typical instance the patient is acutely ill for several weeks or a month or two but almost always recovers his health, at least temporarily, on the absorption of the fluid. It is safe to conclude that the sudden occurrence of an effusion in a young person who has been previously well, and which cannot be attributed to pneumonia, infarct, rheumatic fever, blood dyscrasias, the congestion of heart disease or the transudation in kidney disease, is undoubtedly due to tuberculosis whether tubercle bacilli are or are not found in the fluid. Although it is believed that the most dangerous period after pleurisy is the five years immediately following, pulmonary tuberculosis developed in two of the author's patients seven years after the effusion, and in Kallner's series it was diagnosed eleven, twelve, fourteen and sixteen years later. The mortality from the later pulmonary disease is from 20 to 25 per cent. Kallner points out that, of 605 patients with pulmonary tuberculosis treated at his hospital, 19 per cent had pleurisy before pulmonary tuberculosis developed, while Fishberg, from a compilation of statistics, concluded that between one third and one half of the patients receiving treatment for pulmonary tuberculosis had had pleurisy before symptoms referable to their lungs manifested themselves. It would appear that present concepts of after-treatment of so-called idiopathic pleurisy may have to be changed to prevent in future the present needlessly high tuberculous morbidity. The author suggests that artificial pneumothorax should be instituted on the side affected by the pleurisy and maintained for a number of years if possible as a means of preventing the subsequent development of pulmonary tuberculosis, which almost invariably affects the lung underlying the effusion. Every case of pleurisy should be considered one of potential tuberculosis unless some other cause for the effusion is found. These patients should receive the same repeated observations, from the public health standpoint, as those with pulmonary tuberculosis.

Comparison of Tuberculin Tests.—Court tested two groups of children by the tuberculin patch test and the intracutaneous Mantoux test. The first group of 110 children were tested in a routine manner without regard to age, sex or clinical diagnosis. The ages ranged from 11 months to 12 years. There was no discrepancy between the two methods in this group. The second group consisted of 100 children in whom a positive reaction to 1:1,000 old tuberculin intradermally was established. Comparison with the Vollmer patch test gave 100

Mantoux positive, ninety-eight patch positive and two patch negative. These results agree in the main with those from similar investigations. Some of the advantages of the patch test are that the Mantoux reaction is reliable only if the injection is a true intradermal one, with exact amounts of material. The patch test, on the other hand, demands a minimum of manipulative skill. It obviates yet another of the "pricks" to which children are subjected in these days of increasing investigation. There seems to be no tendency on the part of the child to interfere with the patch once it is applied. Solutions of old tuberculin to be reliable must be renewed at least every two months. However, the patch test material, if kept in a cold dry place, will remain reliable for a year. With the patch test general and focal reactions never occur and necrosing local reactions are unknown. One of the disadvantages of the patch test is that it is slightly less reliable than the intracutaneous method. Therefore in the 2 to 5 per cent of doubtful cases the patch test should be supplemented by the Mantoux, a 1:100 dilution being used. The latter, because of its greater range of sensitivity, should be taken as the reliable indicator.

Value of Intradermal Tuberculin Test.—Bradshaw performed 3,010 intradermal tuberculin tests, using 1:1,000 tuberculin. He states that an analysis of these tests suggests that the diagnostic value of the test is underrated, especially in older children. The test enables a diagnosis of tuberculosis to be excluded in three out of four "suspect" cases in children up to 8 years of age, and in one half of those from 10 to 12 years of age.

Sulfapyridine in Cerebrospinal Fever.—Somers treated 143 cases of cerebrospinal fever with sulfapyridine. All treatments had to be carried out under adverse conditions in dusty grass shelters with insufficient and unskilled (though willing) native staff, and patients received the crudest of nursing and food. The condition of the patient and that of the cerebrospinal fluid were the criteria for the amounts of sulfapyridine injected, and the youngest patients, since they were usually the most seriously ill, received proportionately the largest doses; 1.2 Gm. was the maximum when a watery suspension was used and 3 Gm. when it was combined in an oily suspension. Infants tolerated injections of 0.25 Gm. (in 40 cc. of distilled water) intraperitoneally and 0.5 Gm. intramuscularly. Saline suspensions replaced watery ones and gave less pain. No toxic symptoms followed the injection of sulfapyridine. Herpes labialis seemed to be encountered more often in those receiving large injections. Intraperitoneal injections caused a more rapid general improvement than did intramuscular injections. When possible, lumbar puncture was performed after completion of treatment. In most cases the cerebrospinal fluid became clear before the temperature fell to normal. Arthritis of the large joints and stiffness of the neck usually persisted for some days after the general condition had improved, but they caused little inconvenience to the patients. The usual case mortality of

cerebrospinal fever in the Sudan is from 68 to 80 per cent. In the 143 consecutive cases treated with sulfapyridine the case mortality was 10 per cent.

Herpes Zoster and Varicella.—Since the simultaneous occurrence of herpes zoster and varicella in a patient is not common, Ferriman cites such a case. A review in the literature of similar cases indicates that the condition is most common in elderly men, and the appearance of the varicella usually follows the zoster within five days. Such cases support the view that the eruptions are caused by identical or closely related organisms.

Endocrine Disorders of Childhood.—The symptoms for which children with endocrine disorders are likely to come under observation are grouped by Ellis as disturbances of nutrition, growth, development and metabolism. In some instances, psychologic disturbances or mental retardation will first draw attention to an endocrine dysfunction. Fat children are encountered frequently. In some cases the obesity is a matter of great distress, in others it is placidly accepted as evidence of good digestion. In one child it interferes with activity and results in genu valgum; in another it may be associated with robust health, cheerful disposition and full activity. The physician will have to strike the balance between making an un-self conscious child feel abnormal, and making light of the overanxiety and real distress which is often felt by a fat child who has been made a butt. On the basis of the history and physical examination, although the distinctions are by no means rigid, cases can be grouped as (1) primarily exogenous—in which excessive food intake and lack of exercise are the causative factors, (2) primarily endogenous—in which a "personal factor" is suggested by the family history, onset at puberty or normal caloric intake and (3) due to gross endocrine dysfunction (hypothyroidism, hypopituitarism, pituitary basophilism and hyperadrenalism). Cases of this last type are by far the least common. The endocrine disorders liable to cause rapid and extreme wasting in childhood are diabetes mellitus and hyperthyroidism. Pituitary cachexia (Simmonds' disease) and Addison's disease are extremely rare in this age period. Disorders of growth and development include infantilism, cretinism, pituitary infantilism, precocity and virilism. Infantilism may arise from long standing disease of any one vital organ, e. g. kidneys, intestine, heart, lungs or liver, or from generalized infection such as congenital syphilis. There are in addition certain well defined endocrine types. Cretinism represents the most perfect type of infantilism, since not only does the child retain the size and proportions of infancy (as opposed to childhood) but the mental development is correspondingly delayed. There is a varying individual response to treatment. Although every child will show great improvement physically on thyroid administration, the mental improvement may be either complete or negligible. This is not by any means wholly dependent on the age at which therapy is started. Tredgold suggested that this difference in response might well be explained by there being two distinct types of cretinism—one in which there was primary mental defect, with superadded hypothyroidism, and another in which both mental and physical changes were due to a primary hypothyroidism. Gesell, Amatruda and Culotta found that although every cretin

probably makes his optimal individual response if treatment is instituted early, those patients who will ultimately approach mental normality will show an early mental response to treatment and will react best to relatively small doses of thyroid, their limits of tolerance being reached much sooner than in those who will remain mentally defective. Pituitary infantilism may be associated with diabetes insipidus, a variable degree of obesity or local symptoms due to a pituitary tumor. In some cases the condition is familial.

Teeth as Indicators in Tuberculosis.—In discussing the underlying principles involved in the biochemical study of dental conditions, King-Turner declares that through the upsets of metabolism which are exhibited by the teeth it is possible to determine the cause of health and disease, namely colloidal equilibrium and disequilibrium. An upset in the blood reaction to a state of reduced alkalinity will result in a low pH value of the saliva. This in turn will lead to the withdrawal of calcium ions from the enamel of the teeth, and this process will proceed as long as the pH of the saliva remains on the acid side of neutral, so that in time the dentin becomes exposed and it is then that the chief bacteriologic phenomena occur. The reverse happens in an alkaline reaction and calcium ions are actually built into the enamel of the teeth so that in pyorrhea the well known clinical fact is borne out that the teeth are darker in color and denser in consistency. In applying this to tuberculosis the author states that he has been able to investigate the dental condition in conjunction with the tuberculous lesion in a number of cases and he asserts that there is a definite relationship. The active tuberculous lesion occurs alongside an active carious condition of the teeth. In fact, in a few cases that were apparently quiescent the appearance of new active caries in the teeth has been found on investigation to coincide with a flare-up of the tuberculous condition. On the other hand, those with no active dental lesion or with a tendency to pyorrhea have been found resistant to the tubercle bacillus or at least holding their own with evidence of fibrosis with or without a calcium deposit in the lungs. The point that the author wishes to make is this: if a patient who has already a tendency toward an acidosis acquires tuberculosis it is unlikely that he will have sufficient available ionized calcium to calcify the lung lesion. Even when apparently fit he is drawing on his calcium reserves in an endeavor to compensate for his acid tendency, and with the added stress of disease this using up of calcium will be enormously increased. In the alkaline type of case this deficiency is not present. In fact there is an abundance of base in the blood which is easily precipitated. The appearance of the active dental lesion more or less coinciding with an increased activity of the pulmonary condition is itself significant of the fact that an alteration of the soil, the blood reaction, precedes the activity of the tubercle bacillus. Apart from the wholesale extraction of teeth of a person who is obviously ill, the removal of teeth, other than definitely septic ones, in these cases eliminates a useful indicator of the patient's disease and its course.

Exfoliative Dermatitis with Cutaneous Melanotic Pigmentation and Pigmentary Invasion of Lymphatic Ganglions. C. Goedhart.—p. 316.

Progressive Postoperative Gangrene of Skin.—Touraine and Duperrat give a brief outline of the development of progressive postoperative gangrene and review the literature. They say that postoperative gangrene is due to a secondary infection of the cutaneous wound following an intervention on a septic process and that all other etiologic factors are of lesser importance. The primary operation consists either in the opening of a collection of pus, deep or superficial, or in an intervention on a normally infected cavity such as the digestive tube; this operation is always followed by drainage by means of a tube, compress or wick. The authors analyze the initial diseases which necessitated the surgical intervention in ninety-eight cases of progressive postoperative gangrene. Abdominal operations were performed in seventy of these cases, thoracic operations in eleven and the other operation concerned the opening of superficial abscesses. The authors say that approximately two thirds of the patients are males. The time which elapses between the day of intervention and the appearance of the first manifestations of the gangrene, the period of "incubation," lasts nearly always less than two weeks. The lesion usually begins at the edge of the wound, preferably at the point of contact with the drain. It begins as an erythematous spot, which becomes larger on the following day and often purpuric or cyanotic; one or two days later the spot becomes elevated and forms an inflammatory nodule which is violet; later the center becomes blackish and sloughing sets in. Thereafter it is no longer a question of pyodermitis or furuncle but gangrene must be considered. After describing the gangrenous ulceration, the authors say that the general condition of the patients usually remains satisfactory. The temperature generally remains around 38 C. (100.4 F.), but there are some cases in which it rises to 39.5 (103.1 F.) and even 40 C. (104 F.). The authors review the bacteriologic observations in eighty-one cases of progressive postoperative gangrene and find that in thirty-eight of these streptococcal symbiosis existed, but in twenty-four of these the symbiosis of Meleney was not pure but was accompanied by other micro-organisms. In sixteen of the eighty-one cases streptococci were found either pure or associated with other micro-organisms (not staphylococci). In eight cases staphylococci were found either alone or associated with other organisms (not streptococci). In still other cases diverse micro-organisms were found (neither streptococci nor staphylococci). The pathogenic mechanism of postoperative gangrene is not entirely understood as yet. Regarding the treatment, the author says that cauterization of the edges of the wound has given some good results, temporary amelioration or even cure, but in many cases it does not prevent relapses. The treatment of choice is radical excision in the healthy skin, preferably with an electric knife or thermocautery, or, if that is not possible, with an ordinary knife.

Triphasicism of Rapid Wave in Coronary Syndromes.—Laubry and his associates say that, since the first discussion by Pardee and others of the diagnostic value of the Q wave in the course of coronary syndromes, the majority of investigators have devoted their investigations to this alteration of the rapid wave without giving much attention to other anomalous

lies that may be encountered. However, leaving aside the branch-block type of alterations and the microvoltages of the rapid wave, which are characteristic of diffuse lesions, there exists an interesting morphologic type, which is to be found in the coronary syndromes and in arterial diseases; that is, the triphasicism of the rapid wave. This triphasicism has been studied in the third lead by Katz and Slater, who define it in the following manner: After a more or less pronounced R wave and a well developed S wave, there can be observed a second positive wave at the base of the descending branch, from which originates the line which unites the rapid wave with the T wave. The authors criticize the definition which Katz and Slater gave of the triphasicism of the rapid wave, pointing out that their own studies indicate that the triphasicism of the rapid wave must be considered in a more general manner, without limiting its interpretation to the third lead and without rejecting the cases in which the median deflection of the triphasicism is positive. Having observed that the triphasicism of the rapid wave in the different leads is relatively frequent in the typical forms of coronary sclerosis, they investigated this symptom in a systematic manner in all coronary syndromes, in the anginal syndromes and in the course of various arterial diseases. They give brief reports of thirty-two cases and reproduce a number of electrocardiographic tracings. Interpreting the results of their studies, they first discuss the relative frequency of triphasicism of the rapid wave, then triphasicism in acute coronary thrombosis, in the anginal syndrome, in the arterial cardiopathies, in the valvular cardiopathies and in neurotonic manifestations. In the concluding summary they say that the triphasicism of the rapid wave deserves systematic investigation not only in the third lead but in all standard derivations and even in the precordial one. This triphasicism of the rapid wave is observed with great frequency in all cases with myocardial lesions, before all in the arterial disturbances and principally in the aortocoronary disorders in which angina pectoris or myocardial infarct exists. Moreover, it does not represent a deformation that is of fundamental and pathognomonic importance for coronary disorders or even for arterial sclerosis, because it can be observed also in the course of valvular cardiopathies, in certain indefinitely defined myocardial alterations and in some cardiovascular disorders of the neurotonic type. But without having absolute value, this triphasicism of the rapid wave directs the diagnosis toward a myocardial alteration and it suggests especially a disturbance in the coronary circulation. As in all minor alterations of the electric curve, it must be compared on the one hand with modifications of the ST and T waves and on the other hand with the entire clinical picture.

Gynécologie et Obstétrique, Paris

39: 241-320 (April) 1939

Treatment of Convulsive Eclampsia. Gellé.—p. 285.

Dangers of Artificial Delivery of Afterbirth.—Rhenter and Magnin investigated the results that were obtained with the artificial delivery of the afterbirth. Among the 12,760 deliveries that were managed at their clinic in the course of the last ten years there were 392, approximately 3 per cent, in which the afterbirth was delivered artificially. The technic was the classic one, always carried out with the gloved hand and general anesthesia. In 267 of the 392 cases the artificial delivery of the afterbirth was indicated by excessive hemorrhage, in twenty-four by retention (in two of these by placental impaction, in one by true adhesions and in the others by incarceration with or without generalized uterine contraction); in nine cases the artificial delivery was indicated by atypical conditions (three times following premature detachment of the placenta and six times in placenta praevia); finally, in ninety-two cases there was no special indication, the maneuver having been made following an obstetric intervention practiced under

general anesthesia. At this clinic the incidence of artificial delivery of the afterbirth is somewhat higher than at two other clinics mentioned. Comparing the morbidity rate after the artificial delivery of the afterbirth with that after the spontaneous delivery, they find that it is 12 per cent higher. In the conclusion they emphasize that the indications for the artificial delivery should not be extended beyond those that are necessitated by abundant hemorrhages and by relatively prolonged retention. Moreover, the prophylaxis of these two complications is of primary importance. After citing results obtained by Snoeck and Bernard with injections of posterior pituitary, they report their own experiences with this form of prophylactic treatment. They reserve it for multiparas whose previous deliveries have been difficult or complicated by severe hemorrhages. They inject 10 units of posterior pituitary in the minutes which precede the expulsion of the infant. They have practiced this prophylactic treatment so far in 255 cases and the results have been encouraging.

Traumatic Diabetes. F. Pedrazzini.—p. 707.

Alkaptonuria and Its Treatment. L. Mosonyi.—p. 708.

Migraine and Glycemic Perturbations.—After reviewing the literature on the behavior of the blood sugar in patients with migraine, Girard and Colleson report a case of migraine. A woman 18 years of age suffered from recurrent headaches, which appeared about once a month and were accompanied by vomiting. Medical advice was asked when she had a transitory paresis of the arms and of the right leg with aphasia, which persisted for about half a day. Immediately after this the typical symptoms of migraine developed with several attacks of vomiting. Acetylcholine and sedatives effected no improvement. Attacks of migraine recurred about three times a month. On the supposition that hypoglycemia might play a part, the sugar content was determined between attacks but to the great surprise of the authors it was 1.46. On the basis of this observation it was decided to restrict the carbohydrate intake. After the restricted diet had been continued for a month there was no improvement; the attacks recurred with the same frequency as before. The sugar content between attacks was now 0.99. In spite of this low sugar content the restricted diet was continued, but after five more months the frequency of the attacks had not yet changed. It was now decided to abandon the restriction of the carbohydrates, but the attacks of migraine recurred as before. Several months later a specimen of blood was withdrawn during an attack and it was found that the sugar content had the abnormally low value of 0.58. It was now decided to change the diet to one with a high carbohydrate content. In response to this treatment the attacks of migraine ceased at once. The favorable results of this diet continued for three years, that is until after the woman became pregnant. During the third month of pregnancy the attacks of migraine recurred. In the discussion of this case the authors express the opinion that there is a pathogenic connection between hypoglycemia and migraine.

Revue Française de Pédiatrie, Paris

14: 545-664 (No. 6) 1939

*Investigations on Action of Sodium Chloride in Nurslings. L. Garot, O. Gulko and C. Gottschalk.—p. 545.

Water and Chloride Exchanges in Dehydration of Nurslings. L. Garot, O. Gulko and C. Gottschalk.—p. 588.

New Studies on Cases of Anterior Poliomyelitis Observed in Alsace After Epidemic of 1930: Kinesitherapy of Poliomyelitis. R. Meyer.—p. 627.

Action of Sodium Chloride in Nurslings.—Garot and his collaborators point out that the phenomena of hydration are of great importance in nurslings. They aimed to study the action of sodium chloride, which was ingested with the food in large or small doses, on the water exchange; to specify the mode of retention of the chloride and sodium ions; to determine the indirect or late action of the ingestion of chlorides on the

increase in weight, and to verify their influence on the excretion of potassium. The authors describe their observations on twelve nurslings, all of whom were between 1 and 5 months of age. The alimentary state and digestive function of the infants were normal but their nutritional status varied. The interpretation of the results is rendered difficult by the existence of considerable individual variations. Nevertheless, on the basis of their observations the authors arrive at the following conclusions: 1. Sodium chloride, acting in strong or weak doses, is not bound to the water balance by a quantitative ratio. The observed hydration reactions are moderate and transitory, independent of the rate of retention of sodium chloride. 2. The organism of the nurslings retains a portion of the ingested salt. This ingestion varies between a few centigrams and several grams; it is effected without fixation of water in the great majority of cases. The retention of the chloride and sodium ions is not effected habitually in the ratio of sodium chloride, 0.64; there is in certain cases a profound dissociation of the salt, since the retention ratio Na/Cl varies between 0.45 and 1.88. 3. Sodium chloride provokes important reactional changes in the diuresis and in the insensible perspiration. These changes do not obey uniform rules; they are effected in various directions, but in general their resultant is a reaction of equilibrium which is opposed to variations in weight. 4. Large doses of sodium chloride have harmful effects, which persist for one or two weeks; they consist, in addition to fever, in a slowing up or an arrest of the increase in weight. The small doses of sodium chloride promote growth; this action is prolonged when the organism has restored almost completely the ingested salt. 5. The elimination of large quantities of sodium causes lowering of the excretion of potassium; the elimination of small quantities of sodium influences the excretion of potassium sometimes more and sometimes less.

Radiologia Medica, Milan

26: 373-474 (May) 1939. Partial Index

- Roentgen Study on Development of Pulmonary Cavities. E. Vitale.—p. 373.
Duodenal Ulcer in Children. G. Bignami.—p. 394.
Roentgen Treatment of Lymphogranuloma. G. Giordano.—p. 429.

Roentgen Treatment of Lymphogranuloma.—Giordano reports results of roentgen treatment in 102 patients with lymphogranuloma (Hodgkin's disease) who were under his observation from 1926 to 1937. The group included sixty-five men and thirty-seven women ranging in age from 11 to 80 years. The age of greatest frequency was between 21 and 30. The diagnosis of the disease was verified in seventy-six cases by biopsy, in eight by microscopic study after necropsy and in eighteen there was only a clinical and radiographic diagnosis. The irradiations were given as follows: from 160 to 180 kilowatts, 2 milliamperes through a filter of 0.5 mm. of copper plus from 2 to 3 mm. of aluminum, and at a focal distance of 50 cm. in cases in which the disease was located superficially and from 30 to 40 cm. when the disease was deeply located. At each treatment 250 roentgens was administered. The surrounding zones of skin were carefully protected from the irradiations. The duration and number of treatments were graduated according to individual cases. Generally the irradiations were given in turns so that a given field had the irradiations at intervals of two or three days. In cases of resistance to the roentgen treatment, curietherapy was administered. In cases of great diffusion of the disease Palmieri's method of "superteleroentgen therapy" was resorted to. The method consists in irradiating the whole body with two ampules (one under the other) at a distance of 3.5 meters from the level of the bed. The dose is 180 kilowatts, 4 milliamperes, through a filter of 0.5 mm. of copper plus 2 mm. of aluminum, in doses of 25 roentgens for each treatment, with a duration of two hours. The treatments may be given at intervals of four or five days. The author found that curietherapy and superteleroentgen therapy give immediate satisfactory but transient results. The results of the roentgen treatment depend partly on the location and type of evolution (acute or chronic) of the disease and partly on opportune administration. The best results are obtained when the treatment is administered early in the development of the disease. In the author's cases, duration

of life after the treatment was more than three years in forty-five cases and more than five years in twenty-one cases. Only eighteen patients in the whole group, who did not show recurrence of the disease during the period of survival from the treatment, were able to resume work afterward. The author considers early local roentgen therapy the treatment of selection in the disease.

- *Conic Amputation of Neck of Uterus (Sturmdorf's Operation) with Electric Bistoury. D. González Mármol.—p. 177.
Lymphosarcoma of Stomach. R. Vega Umpierre.—p. 217.

Amputation of Neck of Uterus.—González Mármol performed Sturmdorf's operation by means of the electrical bistoury in ninety-six cases of chronic cervicitis which had been resistant to all local medical treatments. The operation was done either alone or in association with or after some other operation on the internal genital organs. In all cases regional or local anesthesia (spinal, local, epidural or sacral) was administered. The technic followed by the author is as follows: (1) The vaginal flap is previously dissected by the acusector, (2) the base of the cone is delineated and the cone shaped out and resected by the acusector also, (3) the flap of the vaginal mucosa is apposed to the bleeding surface and sutured with a few stitches and (4) a Hegar sound is introduced every other day during the cicatricial period in the newly formed orifice of the neck to prevent closing of the orifice. The author found that the operation gives satisfactory results and has the following advantages: The technic is easy, the exeresis is uniform, the hemostasis is good, the scar left by the operation is small and of a cosmetic aspect, and immediate or late hemorrhages and local infection do not complicate the operation, which does not interfere with the function of reproduction of the patients. The electrical bistoury sterilizes the tissues while cutting them and occludes the lymphatic vessels with which it comes in contact. By these facts local infection, regional lymphangitis and propagation of cancer in the presence of precancerous lesions or of early cancer in the neck are prevented. Pregnancy took place in many of the patients three or four months after the operation. Pregnancy, labor and the puerperium were normal in all cases.

Circulatory and Respiratory Correlations.—Bickenbach shows that all tests which have been recommended for the determination of the functional capacity are inadequate for the estimation of the general functional capacity of a person. Although the analytic tests are important for physiologic research, they are insufficient for the practical requirements of selection for athletic activities, military service and so on. In this paper the author reports studies on twenty-one persons, all of whom were free from metabolic, circulatory and respiratory disorders. According to their constitutional type they were classified into three groups: athletic, normal and asthenic. The cardiac minute volume, the beat volume, the utilization of oxygen and the dissociation capacity of the oxyhemoglobin insure with the external respiration an adequate oxygen supply for the working tissues and the removal of the metabolic waste products from the tissues. The author studied the correlative behavior of these factors in the aforementioned constitutional types. None of the examined circulatory and respiratory factors serve as a measure of the functional capacity of the person in question; together, however, they show a characteristic correlative behavior in the different constitutional types. The

basal metabolic rate is low in the asthenic person, but the oxygen consumption during rest is not reduced in proportion to the functional weakness. The reduced oxygen consumption of the asthenic person requires only a reduced minute volume; it is carried with approximately the same pulse frequency; that is, with a proportionate low beat volume. The minute volume per kilogram of body weight shows the strongest, the minute volume per square meter of body surface shows the smallest, individual fluctuations in asthenic persons. The blood profusion during rest is greater in the athletic person than in the asthenic person. The circulating quantity of blood is noticeably reduced in the asthenic person but not to the same degree as is the minute volume; from this observation the author deduces a uniform dilatation of the arterioles of all capillary regions in asthenic persons and the slight importance of blood depots in healthy persons. The circulation time is considerably prolonged in asthenic persons and this prolongation explains the greater withdrawal of oxygen from the blood and the greater arteriovenous difference in oxygen in asthenic than in athletic persons. Asthenic persons compensate for their reduced oxygen requirements by an accelerated superficial respiration. Citing comparative values observed in normal and in athletic persons, the author shows that the circulation of asthenic persons works uneconomically and this explains the comparatively slight margin of adjustment and the low functional capacity of the asthenic person.

Articular Rheumatism in Exophthalmic Goiter.—Veiel says that generally articular symptoms are absent in patients with exophthalmic goiter. However, a chronic polyarthritis has been described repeatedly as a rare accompanying symptom of exophthalmic goiter. To be sure, some investigators have denied a causal connection between polyarthritis and exophthalmic goiter. The author says that in the course of the last four years he has observed eight cases in which there were articular disturbances among seventy cases of exophthalmic goiter. He reports the clinical histories of these eight cases and shows that in four of them a connection between the articular rheumatism and the exophthalmic goiter may be regarded as proved. In these cases the polyarthritis had developed gradually and without increase in temperature in the course of a typical hyperthyroidism and it had disappeared, together with the other symptoms of exophthalmic goiter, after roentgenotherapy or surgical treatment of the goiter. In accord with reports in the literature, the author observed that this thyrogenic arthritis does not differ in its clinical aspects from other chronic arthritides or arthropathies. Apparently it affects first chiefly the large joints (shoulders, knees, hips), but it may attack also the joints of the fingers. It has in common with rheumatic polyarthritis the tendency to attack several joints successively. Effusion into the joint was observed in none of the cases of thyrogenic arthritis and severe degrees of swelling were observed only once. Stiffening and deformities of the joints, which had been reported by some authors, were never observed by Veiel. The roentgenographic aspects of the joints were on the whole normal. It seems to be characteristic for the cases of thyrogenic arthritis that they fail to respond to the pyrazolon preparations, which are usually quite effective in other forms of arthritis. Large doses of aminopyrine were effective in none of the cases and salicylates and physical measures were likewise without effect. However, treatment with iodine usually produced a noticeable improvement in the articular symptoms of thyrogenic arthritis, as did also roentgen or surgical treatment of the goiter.

Tonsils and Growth.—Disregarding the dispute about the value or worthlessness of the tonsils, Pohl gives his attention to the possible existence of a growth factor in these lympho-epithelial organs. After citing contradictory observations on this problem from the literature, he describes his own studies. He is able to demonstrate on growing viviparous fishes and on young axolotls that the addition to their food of dried substance from the tonsils of hogs resulted in an increase in size which was considerably in excess of that obtained in the control group that was given an addition of the same substance after it had been irradiated. In a second control group, which was given dried spleen from cattle instead of the tonsil tissue, the growth was considerably less than that of the groups fed with tonsillar substance. From this the author concludes that dried tonsillar substance contains a growth promoting substance. In this respect his studies contradict those of Griebel, Voss, Ricci, Meano, Peller, Scheer and others but corroborate those of Slobodnik, Reichmann, Hattori and others. Pohl's observation that even irradiated tonsillar substance contains growth promoting factors, although not in the same quantity as does unirradiated tonsillar substance, contradicts the assertions of Voss and Griebel but confirms those of Reichmann. The author suggests that the contradictory observations on the growth factor in the tonsils might be explained on the basis of observations made by Skoog. This author observed a considerable decrease in the rate of growth in embryonal fibroblasts following the addition of tonsillar extract; however, this inhibition of growth was not observable when sterile tonsillar extract was used, whereas extracts of the bacteria obtained from the tonsils did inhibit the growth. Thus, this inhibition must be regarded as an impairment by bacterial toxins. If it is taken into consideration that this bacterial content is dependent on age, nutrition and individual metabolic factors, as well as on local and seasonal factors, it becomes clear why experiments with tonsillar substance produce such divergent results. After citing studies which make it appear likely that the tonsils have an endocrine function, the author says that additional studies will be necessary to reach a definite conclusion on this problem.

Operative Removal of Fetus in Fetu.—Von Haberer reports the case of a girl aged 4 years who was observed by the parents to have a prominent enlargement of the abdomen at the age of 2 years. This was diagnosed one year later as Hirschsprung's disease. Examination at von Haberer's clinic revealed a marked enlargement of the abdomen, particularly on the left side, and a palpable tumor the size of a child's head. The blood picture spoke against a splenic tumor and intravenous pycelography revealed normal kidneys. Roentgenography demonstrated a normal colon and a large shadow with calcified foci within it. At operation the author found a large intra-abdominal tumor the freeing of which required dissection

of the adherent transverse mesocolon, ligation of the left renal vein, removal of a normal left kidney and the unwinding of the pedicle of the tumor from adhesions to the pancreas and the left adrenal. The tumor when removed was about the size of a man's head and weighed 2,400 Gm. A roentgenogram of the tumor revealed a head, the bones of a well developed upper extremity and below a number of other bones. Thus the tumor was a fetus enclosed within a twin sister and developing at her expense. When the specimen was preserved, incision of the sac demonstrated readily a head and a well developed upper extremity, while at the opposite pole the genital anlage could be recognized. The child made an uneventful recovery.

Lead of Urine and Lead Poisoning.—Reith and van Dijk say that acute lead poisoning is rare and that the cases that are encountered in practice are usually of the chronic type or are marginal cases in which it is desirable to corroborate the diagnosis by chemical examinations. Lead may enter the organism by way of the lungs, the gastrointestinal canal and the skin. With a normal diet and a normal way of life, every person takes in a certain amount of lead and this normal lead intake has been estimated at from 250 to 500 micrograms a day. The elimination of lead from the organism has been repeatedly investigated and it has been established that the largest quantity is eliminated by way of the feces. As regards the urine, it has been determined by some that approximately one tenth of the lead taken in with the food is eliminated with the urine. Although the lead content of the blood has received considerable attention in recent years, the urinary elimination of lead is still regarded as an indicator of the severity of lead poisoning. However, the estimation of the urinary lead content is hampered by the lack of agreement on the normal lead content of the urine. Consequently the authors studied the lead content of the urine of 102 normal persons. They made their tests with the dithizone (diphenylthiocarbazon) method. In the urines collected during a twenty-four hour period the values varied between 8 and 59 micrograms, but in 98 per cent of the cases the lead value was below 50 micrograms. Calculated per liter of urine, the figures were between 5 and 39 micrograms (in one case 55 micrograms). Thus the lead content per liter remained below 40 micrograms in 99 per cent of the cases. The author emphasizes that in making these tests it is necessary to know that bismuth is a possible source of error, as it reacts with diphenylthiocarbazon almost like lead.

Real and So-Called Vitamin C Deficiencies.—Kreuzwendedich von dem Borne surveys the experiences with the determinations of the vitamin C content of the blood and urine and with the so-called saturation tests. He thinks that, in view of the fact that even in normal persons it is necessary to administer five or six times 300 mg. of ascorbic acid before saturation is accomplished, it would be better to speak of

saturation values than of vitamin C deficits. He regards it as erroneous to draw conclusions merely from a single determination of the vitamin C content of the urine but shows that in order to determine the saturation values it is necessary to employ several tests. The vitamin C content of the blood should be determined before as well as after the administration of vitamin C, saturation tests should be made with daily oral administration of 300 mg. of ascorbic acid, and after saturation it is necessary to determine the urinary elimination of vitamin C in twelve hours. In this manner it is possible to determine the cases in which the intestinal resorption of vitamin C is impaired. In various types of anemia the author found no noticeable deviations. Outside of an increase in reticulocytes, the administration of vitamin C produced no therapeutic effect. In hemorrhagic diathesis (Werlhof's disease, Henoch-Schönlein's purpura, hemophilia and so on) the author observed neither deviations nor therapeutic effects. To be sure there seem to be cases of so-called essential thrombopenia, which are the result of a C avitaminosis. The author observed vitamin C deficits also in several cases of peptic ulcer. He thinks that this might be the result of a restricted diet. Moreover, the vitamin C requirements seem to be increased in patients with peptic ulcer, but the efficacy of the administration of vitamin C is still doubtful in these cases. In patients with chronic polyarthritides, the administration of vitamin C is apparently ineffective. In nontropical sprue the absorption of vitamin C seems to be impaired and for this reason it is necessary to administer large quantities of it. In leukemia the administration of vitamin is of no therapeutic value. The author reaches the conclusion that true deficits of vitamin C are rare and that there is no justification for the prevailing tendency of prescribing vitamin C for many different conditions. In cases in which vitamin C seemingly produces therapeutic results it should first be determined whether a hypovitaminosis actually exists. To ascribe to a deficiency in vitamin C an etiologic significance in various disorders is even less justified. Moreover, it should be considered that the intake of natural vitamin C in citrus fruits is probably not only cheaper but also better than the administration of expensive synthetic preparations.

Fermentative Dyspepsia and Fermentative Enterocolitis.—Holmgren says that intestinal fermentative dyspepsia or fermentative diarrhea is characterized by the fermentation of carbohydrates in the intestine. Although it has been generally accepted that the disorder is merely functional and has no anatomic foundation, the author is convinced that it is possible to demonstrate anatomic changes and that fermentative dyspepsia is really an infectious disease, a fermentative enterocolitis. Since 1923 he has replaced the term fermentative dyspepsia with fermentative enterocolitis or enterocolitis with an iodophil flora. That this disorder has received little attention in medical text books is ascribed by the author to the fact that the mild forms are often overlooked and that the disorder is probably not as frequent in other countries as it is in Sweden. The symptoms which induce the patients to seek medical advice are abdominal pains, which are caused by the excess of gas in the intestine, unformed stools and lack of appetite. The symptoms are often provoked or intensified by foods that have a high cellulose and starch content. The patients frequently show slight pallor, a mild anemia and meteorism. The feces, which are unformed and of the consistency of pulp or paste, give an acid reaction and have a repugnant odor; if they are placed in a glass jar it is possible to observe the fermentation. Microscopic examination of the feces discloses an iodophil flora. The author reviews the bacteriologic studies on fermentative enterocolitis which were conducted by Nanna Svartz. This investigator encountered several species of Clostridium, but the predominating one was Clostridium butyricum iodophilum. Another organism to which this investigator gave especial attention was Bacillus perfringens. Following the review of these bacteriologic studies, the author reports his studies on the gastric secretion of patients with fermentative enterocolitis. He shows that a large percentage of these patients have an insufficiency of the hydrochloric acid secretion of the stomach. Moreover, persons with achlorhydria and hypochlorhydria are subject to fermentative enterocolitis much more frequently than is the population in general.

RENAL TUBERCULOSIS AS A COMMUNITY PROBLEM

CHAIRMAN'S ADDRESS

WILLIAM P. HERBST, M.D.
WASHINGTON, D. C.

This address is dedicated to the prevention of deaths caused by renal tuberculosis. The saving of a life by nonspectacular means is just as valuable economically as one saved by the most brilliant surgical operation. The factors involved in this problem consist of conditions which influence (1) the recognition of the presence of the tubercle bacillus in urine, (2) the general resistance of the individual, (3) the mortality from procedures instituted in treatment and (4) provision of adequate facilities and detailed direction of every individual affected.

RECOGNITION OF THE PRESENCE OF THE BACILLUS

The recognition of the presence of tuberculous involvement of a kidney or kidneys is dependent on urographic evidence of renal tissue destruction and the finding of the tubercle bacillus in urine from the kidney. When to look for the tubercle bacillus is important. The following conditions indicate the advisability of a search: 1. Unilateral renal infection. 2. Hematuria with no obvious explanation. 3. Pyuria with no organisms demonstrable by ordinary staining methods. 4. Persistent pyuria of any kind. 5. Cystitis which does not respond to a reasonable period of treatment. 6. Pyuria or dysuria in individuals with a history of tuberculosis or active extra-urinary tuberculous lesions; nodular lesions in the seminal tract. 7. Urographic evidence of the destruction of renal tissue.

The technic of recognizing the presence of the tubercle bacillus is far from being uniform and is unsatisfactory so far as the cross section of this activity is concerned. It was Dr. Keyes who some years ago compared the percentage of accuracy in finding tubercle bacilli in his private cases as contrasted to those in ward cases. He found that his own percentage was about 90 and that of the ward cases about half the latter figure. Cultural methods have been found to be rather accurate in the hands of a few technicians. Eisendrath in a study of 424 cases of renal tuberculosis found the culture to be positive in nearly all and a smear positive in 351. Of 124 cases which were found in the literature in which the comparison between cultures and guinea pig inoculations was reported, the cultures were found to be positive in sixty-one and the guinea pig inoculations positive in fifty-five cases. The largest number of cases

in which the three methods were compared is that of Dimtza (cited by Eisendrath). In eighty-one cases a smear only was positive in fifty-eight, the guinea pig inoculation in seventy-six and cultures in eighty. These figures do not give an accurate picture of the problem as it exists because they are reports of individuals who are much more careful of their work than the average of the profession at large. The common practice in many laboratories in searching for the tubercle bacillus is to accept whatever specimen or specimens are presented to them by the physician and render a report. Unfortunately, in many instances they refrain from embarrassing a physician sending in the specimen by insisting that he send in multiple specimens for staining or, in the case of a specimen for guinea pig inoculation, that he send in not less than three specimens which are to be injected into a pig or pigs. The question of staining methods is very important, but the most important factor is that of experience, which makes the difference between the 90 and the 45 per cent reported by Dr. Keyes. The technical facilities in the nature of cystoscopic facilities is important. In the nation's capital, astounding as it may seem, the newly constructed city tuberculosis sanatoriums for adults and children do not have an equipped cystoscopy room. This is a lamentable situation which should not be allowed to exist in any community.

GENERAL RESISTANCE OF THE INDIVIDUAL

The entity called general resistance is the most important single factor in the whole picture, since it is the handling, consideration and conservation of this factor which ultimately results in recovery or death. The various health department statistics demonstrate the influence of the general resistance factor of the economic status in the extreme preponderance of Negro as compared to white deaths. In the nation's capital the mortality from tuberculosis in all forms is about three times greater in the Negro than in the white race. Renal tuberculosis is supposed to be present in about 5 per cent in all cases of tuberculosis. Thomas found it clinically in 3.87 per cent of the patients admitted to Glen Lake Sanatorium and with additional cases by autopsy making a total of 5.5 per cent. In the city of Detroit, where the tuberculosis problem is supposed to be well handled, we find that the mortality among the Negroes is over six times as great as in the white population. The economic status of any community is a factor which is important but which we as a profession can do little about. We all have seen patients advised of the necessity of long hospitalization refuse because of the responsibility for their dependents, only to return subsequently with a condition which proved to be fatal. Dr. Morris Fishbein explained to the National Health Conference that the economic status of the population was more

Read before the Section on Urology at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 18, 1939.

vital than extravagant ideas advised by some at that conference. This was a concrete example of advice on the part of the profession. The profession should go a step further, however, and be constructive, as it can well be in any community, by enlisting cooperative public group pressure, with appropriate publicity, on legislators to appropriate adequately for maintenance of the breadwinner's dependents when they are ill. We can also get behind movements directed toward the elimination of slums, where tuberculosis has its greatest incidence. The matter of climate is important. Dr. W. C. Shultz of Tucson, Ariz., stated: "I rarely find genito-urinary complications in patients who have been residents of Arizona for any period of time." Dr. Don Augusto S. Boyd, ambassador of Panama, who is a prominent surgeon, told me that renal tuberculosis does not exist in Panama though there are many cases of pulmonary tuberculosis. Of course, climatic treatment cannot be applied to the indigent, but it is very important to prescribe a favorable climate for those who can afford it. Ultraviolet radiation and heliotherapy are very valuable in their effect on the general resistance when they are intelligently used, and Wang even employs them intravesically. Two very important precautions should be observed: Ultraviolet radiation is definitely contraindicated in patients with pulmonary tuberculosis and should never be administered to the point where it produces fatigue. Because of failure to observe these simple precautions, many patients have succumbed from overtreatment. The influence of diet on the resistance is also important. The diet should be abundant and well balanced but not forced to the point of gorging. It should be rich in vitamins, and usually it is wise to supplement it with vitamins in concentrated form. The diet should include at least one quart of whole milk daily, taken either at mealtime or between meals (Dr. Charles P. Cake). Rest is highly important, and the patient should not be expected to engage in any strenuous physical activity of any kind after nephrectomy for varying periods ranging from several months to two years, depending on the physical condition. Of course, a patient with active tuberculosis anywhere else in the body must have continuous bed rest. Another important measure in the management of patients with renal tuberculosis who have no open lesion is to be sure that they are not exposed to patients with open lesions in wards. This is not possible in many communities today because of a lack of beds for this type of patient. Some of the health departments have no definite policy in this regard, probably because they have no facilities with which to pursue any policy.

MORTALITY FROM PROCEDURES INSTITUTED IN TREATMENT

There are many variables in this phase of the problem. First of all, the type of tuberculosis of the kidney varies. There are cases in which a single lesion exists and heals spontaneously without being recognized. The number of these is naturally indeterminate. Next there is the chronic form which starts as a minute lesion below the surface of the papillae and progresses very slowly to varying degrees of erosion, cavitation, fibrosis or abscess formations extending throughout and beyond the kidney. In a few of these cases atresia of the ureter occurs with spontaneous autonephrectomy. There is controversy over the so-called tuberculous nephritis which Wildbolz claims exists and Lieberthal and others question. The acute miliary type is a very rapidly developing process which is a part of a general miliary

tuberculosis and rapidly fatal. From a practical standpoint the treatment instituted applies to the group of chronic types. Nonoperative treatment presumes that the patient is too gravely ill to withstand surgery or that his response is good and therefore a chance for spontaneous cure exists. The greater number of authorities deny that tuberculosis of the kidney ever heals. Thomas and Medlar champion the view that renal tuberculosis can and does heal. I believe that tuberculosis of the kidney does heal because I have seen at least two cases in which involvement of the remaining kidney after nephrectomy for renal tuberculosis became arrested. What is more important to my mind is the untenability of the position that renal tissue cannot heal when pulmonary, glandular, peritoneal, and other tissues can. Wildbolz reported 316 nonsurgical cases in which 58 per cent of the patients died in five years or less and in which 6 per cent lived more than ten years. He states that only two cases of spontaneous healing had been reported up to 1932. He reports a recovery in 86 per cent of nephrectomized patients when no other lesions existed, and 43 per cent when genital lesions coexisted. Thomas has followed many cases for years under constant observation. All things being equal, the great preponderance of data justifies early nephrectomy, and the earlier the recognition the better the results. In view of the fact that renal tuberculosis does heal, even in rare instances, the postoperative care is most vital. All the factors enumerated under general resistance should be scrupulously observed and employed in order to reduce greatly the ultimate mortality. All authorities agree that the postoperative care is very important. Their policy varies anyway from the giving of general directions to prolonged sanatorium and climatic care, even in cases uncomplicated by active tuberculosis elsewhere. It is my opinion that in the uncomplicated as well as the complicated cases a minimum of a year's constant supervision of the urine should be given and if economically possible I would send everybody to a climatic environment such as Arizona for not less than a year. We must be practical, however, and meet the problem as satisfactorily as we can, striving constantly to improve the economic factors in our own communities.

PROVISION OF ADEQUATE FACILITIES AND DETAILED DIRECTION OF EVERY INDIVIDUAL AFFECTED

The medical society should make a survey including the status of clinical laboratory facilities for the detection of the tubercle bacillus in urine, the resources available for taking care of resistance factors of the indigent and the number and kind of beds available for tuberculous patients. Having done these things, it should urge ample provision of cultural facilities in all private and hospital clinical laboratories, influence the health department to furnish cultural facilities in its laboratories equal to those for diphtheria, meet with and enlist cooperation of all lay organizations and health departments in acquiring public funds for two and one-half beds per death, and carry out social service care of dependents, elimination of slums where tuberculosis is preponderant, and work for general improvement in general standard of living conditions.

On a national scale, the laboratory men, professional tuberculosis societies and urologic groups should standardize cultural and other clinical laboratory investigation methods for the detection of the tubercle bacillus in urine and urge the profession to use them.

Community action on the part of any medical society along these lines will result in some degree in dispelling prevailing public opinion that we are obstructive to their acquisition of cheap or free medical service and, what is more important, will stamp physicians as authoritative, dynamic and sympathetic leaders in solving community health problems.

1801 I Street N.W.

THE TREATMENT OF MASSIVE HEMORRHAGE DUE TO PEPTIC ULCER

JOHN S. LA DUE, M.D.

MINNEAPOLIS

All patients with hematemesis and melena due to peptic ulcer admitted to the Long Island College Hospital are fed immediately and repeatedly. This treatment has been employed in all ward and in a majority of private cases during the last eighteen years.

The therapy was devised by Dr. Andresen¹ in 1916. He first gave gelatin mixtures to patients recovering from a gastro-enterostomy with such favorable results that he decided to give the same mixture to patients with gastric hemorrhage.

Most clinicians advocate a period of fasting, the giving of fluids and transfusions when needed, and rest. Lenhartz² in 1906 treated 146 cases of hemorrhage due to peptic ulcer by feeding eggs and milk immediately. The mortality was 2.14 per cent.

Carlson³ demonstrated that an empty stomach is one in which active peristalsis and secretion take place. After hemorrhage the stomach is empty or filled with blood, usually clotted. The blood with its high protein content acts as a powerful stimulant for the production of gastric juice. A stomach partly filled with food which combines rapidly with any gastric secretion is preferable to an actively contracting stomach full of secretions which are likely to digest the clots plugging the bleeding vessel or even the injured vessel wall itself. Since the purpose of any treatment is primarily the stopping of hemorrhage, it is reasonable to strive to keep the stomach as completely at rest as possible. Equally important is the inactivation of potent gastric secretions.

In 1936 Meulengracht⁴ reported a series of 251 cases of severe hematemesis and melena with a mortality of 1 per cent. The patients were fed five times a day on such foods as meat balls, chops, potatoes, vegetable purées and steamed apricots.

Mortalities reported in the literature are summarized in table 1. Cases in which immediate and repeated feedings are given have significantly lower mortalities than those in which a period of starvation is employed. Only six of the twenty investigators who withheld food report a mortality of less than 10 per cent.

In the therapy for bleeding ulcer to be described here there are four objectives: (1) stoppage of bleeding by

the formation of clots at the site of hemorrhage; (2) prevention of an increase in blood pressure (already low as a result of hemorrhage) so rapid as to dislodge these clots; (3) management of shock, with avoidance of too much stimulation, which often results in recurring hemorrhage, and (4) prevention of the digestion by gastric secretion of the exposed wound in the blood vessel or of the clots filling the defect.

Rest is essential if any one of these objectives is to be realized. Patients must have absolute rest in bed and be constantly reassured, lest fear and its resultant restlessness upset the entire regimen. They are usually morphinized for twenty-four hours, or longer if necessary.

Intravenous and parenteral fluids are not given as a routine, their desirability being far outweighed by the danger of increasing the blood pressure to a point high enough to dislodge clots already formed. Transfusions are avoided when possible early in the treatment for the same reason but are given in amounts of from 200 to 300 cc. if the systolic blood pressure falls below 90 or the hemoglobin content below 30 per cent. Occasionally one such transfusion will carry a patient past the danger point, but it is again emphasized that transfusions are reserved for the exsanguinated, moribund patient and are not given as a routine. After all signs of hemorrhage have disappeared, large transfusions may materially shorten the period of convalescence.

Stimulants are given rarely and with great caution lest the patient's activity be increased enough to cause another hemorrhage. The surface of the body is kept warm and nothing that might cause chilling, such as the use of ice bags over the epigastrium, is employed.

Emesis, melena and retching, always exhibited in some degree, indicate irritability of the gastrointestinal tract. The diet employed is designed to overcome this irritability and hypersecretion.

Table 2 shows the type and schedule of feedings given to patients with hemorrhage due to peptic ulcer. Four ounces of a gelatin mixture (consisting of 30 Gm. of gelatin, 90 Gm. of lactose, 1,000 cc. of water and the juice of an orange for flavor) is fed every one and a half hours except when the patient is sleeping. On the third day 5 ounces of a gruel mixture (made from 500 Gm. of cereal gruel, 420 Gm. of milk, 120 Gm. of cream and 90 Gm. of lactose) is given every hour and a half in addition to the gelatin. On the fifth and sixth days, 6 ounces of gruel mixture 2 (350 Gm. cereal gruel, 1,000 Gm. of milk, 120 Gm. of cream, 120 Gm. of lactose) with 6 ounces of gelatin solution is fed every hour and a half. A poached egg, custard or jello may be added to the gruel after the fifth day. On the seventh and eighth days, feedings are given every two hours. On the ninth day the Long Island College Hospital ulcer diet, a bland diet given without alkalis, is begun.

As the work of Carlson has shown, an empty stomach is never at rest; it appears desirable to keep the stomach as nearly at rest as possible by keeping it partly full. The diet described is adequate in this respect, is soothing and combines rapidly with any gastric juice that may be present. The gelatin solution lessens the distressing thirst exhibited by these patients and supplies more than 1,000 calories and 2,000 cc. of fluid every twenty-four hours. No amount of reassurance is so effective in quieting the patients' worry as the giving of nourishment so soon after hemorrhage. X-ray films

are taken from seven to ten days after bleeding ceases. Hospitalization averages 27.5 days in this series.

In preparation for this report, the gastric hemorrhage cases admitted from 1925 to 1936 inclusive were studied, and only the eighty-two cases that appeared according to all accepted criteria to present genuine ulcers were included.

Seventeen cases failed to reveal evidence of ulcer by x-ray examination, but the gastrointestinal series were made from two to six weeks after signs of bleeding had disappeared and the ulcers had had time to heal. In seven of these cases there were no symptoms prior to hemorrhage; in the other ten there were chronic gastric complaints. Duodenitis was ruled out by fluoroscopic studies.

All patients had had bleeding severe enough to force them to seek hospitalization, and all had bled shortly

two cases (87 per cent), but in ten cases the hemorrhage was the first symptom noted by the patient. In thirty-three cases there was a history of previous hemorrhage.

Gastric analyses were done in forty-nine cases. In twenty-seven an excessive amount of free hydrochloric acid was found and the curve over the two hour period remained elevated; in sixteen approximately normal curves were observed and in five patients (all at least 50 years of age) the acidity was low. The stools gave a positive benzidine reaction for from five to thirty days after entry.

Not one of the patients who died was operated on, and in the two cases in which consent for autopsy was secured the character and site of the lesion precluded any successful surgical procedure, in the opinion of the pathologist, internist and surgeon present at the autopsy.

before entry. Red blood cell counts on admission were less than three million and hemoglobin contents less than 60 per cent. Seventy-six patients exhibited symptoms and physical signs of severe hemorrhage on admission, such as rapid shallow respiration, low blood pressure, syncope and collapse. The remaining six had these symptoms in a lesser degree at some time during their stay in the hospital.

Accepted criteria for hemorrhage from the gastrointestinal tract were hematemesis, melena or both. Of the fifty-four patients found to have duodenal ulcer, two had vomited blood, thirteen had passed tarry stools and thirty-nine had done both. The eleven patients with gastric ulcers both vomited blood and passed tarry stools. Of the eighty-two patients, 75 per cent had a history of hematemesis and melena, 17 per cent of tarry stools alone and 7 per cent of hematemesis alone.

Fifty-eight, or 70 per cent, of these patients were men. Seventy-five per cent were between 30 and 60 years of age. The largest single age group, constituting 30 per cent, was in the 40 to 50 year range. There was a previous history suggestive of ulcer in seventy-

Of the eighty-two patients eight died, seven as a direct result of repeated hemorrhage. Three of these fatalities are not included in the mortality statistics because one patient died of pneumonia contracted six weeks after entry when the hemorrhage had been well controlled; one died in the accident room before treatment could be administered and one was not given feedings. Hence the mortality is 6.3 per cent.

One patient lived eight days after admission, the others an average of twenty-six hours after the onset of their hemorrhage. The fatalities, with one exception, occurred between the ages of 40 and 70 years.

In four of the five cases included in the mortality statistics the Andresen therapy was not strictly followed. One patient did not have an acute gastric hemorrhage, having had tarry stools for three weeks, and the diagnosis of bleeding ulcer was not definitely established. Another was exsanguinated on admission (red blood count 850,000; hemoglobin 10 per cent) and died within twenty-four hours. The third died after a massive transfusion not advocated here; the fourth was given 500 cc. of intravenous dextrose (also contra-

indicated) and died in sixteen hours. Thus the mortality rate in cases in which the regimen outlined was strictly followed is only 1.3 per cent.

When various mortality statistics are compared, variations of from 1 to 20 per cent are found, the rate being consistently higher whenever there was surgical intervention. At one hospital five out of seven patients who were operated on died; at another all died. It is indeed rare that an acutely bleeding patient recovers after a surgical procedure, and the operation, once performed, affords no guarantee of freedom from recurrent hemorrhage, for Balfour⁵ found that 13 per cent of all patients had recurrent bleeding after operation. Hinton,⁶ Westermann⁷ and Hurst⁸ also observed recurrent hemorrhage after surgery. Lynch⁹ reported twenty-one cases surgically treated with a mortality

TABLE 2.—Long Island College Hospital Diet for Patients with Gastric Hemorrhage

	Character of Feedings	Ounces	Grams	Calories
Gelatin solution	Gelatin.....	1	30	128.0

of 42.8 per cent and thirty-one cases medically treated with a mortality of 12.9 per cent. Four of our patients had recurrent hemorrhage following gastric surgery.

It may be concluded that a certain percentage of patients with bleeding ulcer will die regardless of treatment, but the fundamentals of therapy must be met by aiding the physiologic processes of healing. This can best be done by putting the stomach as nearly at rest as possible, inactivating the gastric secretions and maintaining the general nutrition. The modified Lenhartz regimen of Andresen meets all these criteria physiologically and will, it is hoped, find a deservedly wider use in the future.

ABSTRACT OF DISCUSSION

DR. ANDREW B. RIVERS, Rochester, Minn.: All are fairly well agreed that surgical rather than medical treatment is usually the procedure of choice in dealing with massive hemorrhage due to peptic ulcer. However, during or immediately after a hemorrhage the patient is either too sick or not sick enough to be operated on. To rush precipitously and tie off some bleeding vessel as a final gesture to save the life of the patient, it seems to me, is to court disaster. The time to operate on the patient who has bleeding peptic ulcer is in between the hemorrhages and before the final one has started. How shall one proceed when confronted with the necessity of doing something for the patient who has just had a massive gastric hemorrhage? Shall one begin at once on a regimen of feeding this patient? Shall one starve him until all signs of bleeding have stopped or shall one do a little watchful waiting for a few days while gradually restoring physiologic equilibrium, unless gross bleeding requires emergency transfusion? I have been depending mainly on the latter method, varying it somewhat to suit the individual case. The less severe the hemorrhage, the earlier I begin cautious, small, bland feedings. I am less timid about transfusion than is Dr. La Due. I agree with him that one of the important procedures in the treatment of such patients is to keep the stomach as completely at rest as possible. In addition, I should like also to keep the esophagus and the upper portion of the small bowel at rest. Frequently it is impossible to be certain before initiating treatment for gastric hemorrhage regarding the exact cause of such a symptom. Occasionally such an emergency is caused by bleeding esophageal varices. Under such a condition the institution of immediate and repeated feedings, particularly according to the Meulengracht method or after the passage of tubes for drip therapy, might well hinder rather than help the clotting of the blood. Furthermore, I have seen instances in which the restraining clot in a pancreaticoduodenal artery could scarcely have withstood any but the most innocuous gastric chyme impinging on it through a pyloric nozzle. If the gastric chyme can be made innocuous by the addition of gelatin mixtures this would constitute a sound physiologic reason for the use of gelatin after hemorrhages. I am not so convinced that any therapeutic procedure that requires frequent efforts of swallowing can prevent some peristaltic rushes in the upper portion of the gastrointestinal tract. These peristaltic rushes might defeat the purpose of frequent feeding.

DR. KENDALL A. ELSOM, Philadelphia: I agree with Dr. La Due that the treatment of bleeding peptic ulcer by a feeding program deserves a wide clinical trial. In an analysis of this problem last year Dr. Miller and I collected from the literature over 5,000 cases of peptic ulcer hemorrhage that had been treated medically by the usual conservative methods. The mortality was 9 per cent. In 509 similar cases in which food was permitted from the onset of bleeding the mortality was 1.8 per cent. If this striking reduction in mortality is achieved by future observers, a great advance in treatment will have been made. Dr. La Due's paper, since it bears on this point, is most timely. Let us examine whether or not he has demonstrated a reduction in mortality. One of the greatest difficulties in forming a definite conclusion concerning mortality rate is due to the fact that authors use different criteria for including or excluding cases in their statistical analyses. Let me use the data just presented as a case in point. Of the eight fatal cases one death was from pneumonia, not from loss of blood, and is properly excluded in calculating the mortality; one case was not treated with the Andresen diet and should, I think, be entirely excluded. The two in which death occurred before feeding could be instituted must be accepted as deaths from hemorrhage, for I doubt that Dr. La Due would contend that feedings of gelatin would have saved these patients in their moribund state. The two patients who died following transfusion and intravenous infusion can be excluded only if it is certain that these measures were directly responsible for their deaths. By a slightly different interpretation of the data, therefore, it is possible to arrive at a mortality figure of either 1.3 per cent or, according to my calculations, six deaths of eighty-one patients, or 7.4 per cent. If the latter figure is

correct it approximates the average 9 per cent mortality figure for the now current medical methods of treatment and does not establish an obvious superiority for the feeding technic. If the figure of 1.3 per cent is correct the feeding technic is clearly superior. On the basis of the data presented I feel that the lower mortality figure cannot be accepted. However, the main thesis of Dr. La Due's paper is entirely acceptable, and the wonder is that the technic introduced by Dr. Andresen in 1927 has not had wider acceptance in this country. Last year we adopted as a routine the essential elements of this regimen in the University of Pennsylvania Hospital and in ten cases have not yet had a mortality. Certainly the patients are in better physical and mental condition when fed regularly. We have followed the same general principles concerning transfusion that Dr. La Due outlined.

DR. HORACE W. SOPER, St. Louis: In 1931 my paper on the subject of "The Treatment of Hematemesis by the Retention Catheter" was published in THE JOURNAL. At that time I emphasized the use of the No. 16 gastroduodenal catheter in early lavage of the stomach. The catheter is introduced intranasally, contains no metal tip and is shaped like the ordinary urethral catheter, and the clots of massive hemorrhage can be washed out with a large Luer syringe perfectly, without any struggle or inconvenience to the patient. Furthermore, the tube can be easily passed in the unconscious patient. I advocated the early use of both gelatin water and egg albumin water and found that their use did not incite gastric secretion or gastric movements. Neither does the retention of this small catheter incite gastric secretion. About 25 to 50 per cent of the fluid that is put in the stomach passes out through the rubber tube. The remainder passes down into the small intestine. Distention of the stomach is thus prevented. Since that paper was published I have had increasing experience with the method and I feel that it has tremendous value, particularly in cases in which hemorrhage recurs. The physician is always in complete control of the situation. He knows whether or not any further bleeding has occurred. In the event of the recurrent or continued bleeding, one will see the blood coming into the glass tube that is attached to the container on the floor. One may now resort to early surgical treatment. Late surgery entails a high mortality percentage. Since 1931 I have encountered four cases in which early surgery was employed because of this appearance of the bright red blood after lavage, and all four patients recovered. In each instance the surgeon located the spurting artery.

DR. L. WALLACE FRANK, Louisville, Ky.: Dr. La Due has presented an interesting paper. Some of the most severe hemorrhages from the upper part of the gastrointestinal tract do not come from the ulcer itself but are due to erosions in hyperplastic stomach mucosa or the mucosa of the duodenum, and it is of these that I wish to speak. In a small series of cases in the past eight months the amount of blood loss in each varied from 500 up to 2,000 or 2,500 cc. No ulcer could be demonstrated. In this series in every case of hemorrhage the blood prothrombin as determined by the Quick method was 70 per cent of normal or less. These cases in which bleeding occurs from erosions are not surgical cases and the prothrombin level is below normal. The treatment consists in raising the blood prothrombin to normal and then the clot will be sufficiently strong to hold and the hemorrhage will cease. In this small series vitamin K was administered by mouth to raise the prothrombin, and drip transfusions of large amounts of blood were used to combat the blood loss. The transfusion is given relatively slowly and the blood must be taken from donors shortly before it is administered to the patient, as it has been demonstrated that blood kept in a "blood bank" loses its prothrombin value. Prothrombin in the donor's blood may cause temporary cessation of bleeding but to cure the patient it is necessary that his own blood prothrombin be raised to normal.

DR. WILLARD D. MAYER, Detroit: At the Receiving Hospital in Detroit we have used the Meulengracht method. We feed these patients. I must say that we started out with a considerable degree of fear, but our fears were really not justified. The Meulengracht routine consists briefly of a day of starvation at the onset of treatment with intravenous dex-

trose and transfusions as indicated, and then on the following day the patients are fed. We allowed the patients plenty of food; in fact, we gave them more than Meulengracht advised because we found that on his routine the patients had a considerable amount of food in the morning and at noon, but toward evening they were all very hungry so we increased the late afternoon and evening meals. Strange as it may seem, our results were pretty good. We had two deaths in a series of 113 cases. I really do not think one of these deaths should be considered as a death due to the diet, because one patient passed away within forty-eight hours and had but little to eat. The second case was a frank death incident to the diet. We had failures. Fourteen patients had to discontinue the diet because of abdominal pains or relapse of bleeding. These patients were taken off the diet. The treatment was not followed by me alone; it was followed by all members of the staff in the medical service as we wanted to get an unbiased opinion. Dr. La Due and some of the discussers have felt that in the empty stomach there is more vigorous peristalsis and more chance for hemorrhage. It seems to me that deaths in this condition occur either early at the onset or on the sixth or eighth day after the hemorrhage. I believe that with the feeding method those deaths occurring later are perhaps obviated. I would not say that this method is the last word; I think it should be carried on in other clinics and in this way it may be possible really to learn if the method is advisable. We did not have to give these patients large amounts of sedatives and opiates as they were comfortable after a few days, and their period of hospitalization was shortened. I believe there is merit to this routine.

DR. JOHN M. BLACKFORD, Seattle: I have recently reviewed the literature in an attempt to find out what the actual mortality is and have made a study of the subject in a new way. Dr. Cole and I went to the Seattle Bureau of Vital Statistics and took all the certificates of death from peptic ulcer for four years, 216 deaths. Seventy-two of the death certificates mentioned hemorrhage as a factor in death. We went back to the original hospital records of these seventy-two patients, or to their physicians, and found that fifty-five had actually died from hemorrhage. Four of these had died from hemorrhage from a gastrojejunal ulcer and hence should be excluded, leaving fifty-one patients who died from hemorrhage from peptic ulcer. Forty-nine of the fifty-one were above 45 years old, for only two deaths occurred in patients under 45 years of age. Forty-three per cent of the cases came to autopsy. In our experience we have had no deaths from hemorrhage in a patient under 45 years old. We have found, as has every other observer that I know of who has studied the matter in relation to age, that practically all deaths from hemorrhage (provided the surgeon lets the younger ones alone) occur in the older group. The mortality between 50 and 70, as found in various series of statistics, is about 30 per cent if only massive hemorrhages are considered. If all admissions for hemorrhage between these ages are considered, the mortality is approximately 15 per cent. The author has not discussed age groups at all in his paper, and I was a little disconcerted to find that his 1.2 per cent mortality was culled out of eight deaths in a series of eighty-two or eighty-three patients. The interpretation of statistics is always an interesting subject and it does not seem to me that we are justified in eliminating deaths because of some slight variation in treatment. I think it can be stated without any question that, from the practical standpoint, almost no deaths occur from bleeding from peptic ulcer in patients under 45 years of age. I think it impossible that there can be any radical error in our statistics. We are manifestly not using a sampling method when we have investigated all deaths in four years for a city of nearly half a million people. Such statistics are manifestly not based on a "sampling method." Regardless of what method of treatment is used in attempting to control hemorrhage from peptic ulcer, there are practically no deaths from such hemorrhage in patients under 50 years of age.

DR. MANFRED KRAEMER, Newark, N. J.: I want to make two points: First, there is no condition in internal medicine in which individualization is so important as in the treatment of bleeding peptic ulcer. Five years ago every patient who

came into the hospital was automatically put on starvation and then on a Sippy diet. Now every patient is given the so-called Swedish diet. Ulcer patients have to be individualized. An ulcer patient who is vomiting can't be fed. I have seen physicians following a printed routine go ahead and try to feed this Swedish diet to patients who are vomiting. There are many cases in which one has to give intravenous infusions, sometimes for several days. One has to treat the patient and one can't follow a feeding routine. The second point is the diminished importance of considering chemical neutralization of acid by feeding or by alkalis. The use of the gelatin may not be a neutralizing but an adsorptive mechanism. We should consider it thus more of a method of adsorbing (physical) acid rather than of neutralizing (chemical) acid. As time goes on we seem to be getting away from the thought of neutralization.

DR. WALTER L. PALMER, Chicago: I should like to point out that the Meulengracht diet, if it possesses any advantage over starvation, as it apparently does, probably does so by virtue of its ability to neutralize or absorb a certain amount of hydrochloric acid. A number of years ago Sippy advocated the prompt institution of feedings and the use of alkali in the treatment of hemorrhage. I have followed this program in the main for the last ten or twelve years. Because I have had some deaths and some recurrent hemorrhages, I have from time to time tried other methods. I cannot report today a series of cases treated by any one method. In 230 cases of massive hemorrhage the mortality rate has been a little over 3 per cent. Five deaths occurred from exsanguination. One man under 30 died in the fourth hemorrhage. Autopsy disclosed a bleeding artery. Most of the patients have died in their first hemorrhage rather than in recurring hemorrhages. I have concluded that patients should be fed at once if they are not vomiting. I use the old program of Sippy and continue it through the night. One must be careful about alkalosis. Contrary to the chemists, calcium carbonate may produce alkalosis. But if one uses it with magnesium oxide or other forms of magnesia the alkalosis can be partially combated by the addition of salt to the diet. The mechanism of this effect is obscure. I agree with Dr. Rivers and others about the importance and value of transfusions. I believe they should be used early. It is true that the more transfusions one must give, the poorer the prognosis, but I had occasional deaths from not giving transfusions. One recovery occurred after eight transfusions and several after five or six transfusions. I agree that drip feedings and drip methods should be avoided, if possible, because of occasional cases of hemorrhage from esophageal varices and also because with drip feedings there tends to be a dryness of the mouth, which I think contributed to two or three pneumonias complicating hemorrhage. One of these patients died from his pneumonia in spite of massive serum therapy.

DR. S. KENDIG WALLACE, Baltimore: I want to ask Dr. La Due why he didn't mention the use of larostidin in the treatment of peptic ulcer. I have been using it for several years in mild cases as well as in severe cases and with good results. In cases of severe gastric hemorrhage and of perforated peptic ulcer I start off immediately with two doses, that is 5 cc. twice a day, until the patient is out of danger. Regardless of what other treatment is used, I always use these injections as an additional precaution, which I feel is of considerable benefit to the patient.

DR. GORDON H. IRA, Jacksonville, Fla.: I listened to Dr. Andresen's paper in Washington in 1927 when he reported a series of cases in which this diet was used. For eleven years I have used it exclusively on service and private patients, with a very low mortality rate. One severe surgical critic, who treated all his patients with morphine and ice bags, has started using that diet. I want to commend Dr. Andresen's diet as Dr. La Due has reported it.

DR. JOHN S. LA DUE, Minneapolis: I hope to correct any false impression I may have given in discussing our mortality statistics. Some of the deaths occurred before any treatment could be given and are justly omitted in discussing the mortality of treated cases. Patients not receiving the exact treatment outlined here were included in gross mortality statistics. The figure 1.2 per cent was submitted only that you might

know the death rate among patients given the exact regimen of therapy described here and I make no claim that these patients would have lived had this method been strictly followed. Larostidin was not employed in the treatment of our patients and hence we had no chance to appraise it. Dr. Soper's use of a catheter passed into the stomach or duodenum might be a valuable aid in determining which patients continue to bleed profusely and are therefore candidates for surgical intervention. The passage of such a tube and its continued presence near a bleeding ulcer are not without danger, I think. As yet we have no criteria to tell us which patients will die if treated by medical means alone, but surgical mortalities are far too high to make surgical intervention the method of choice except for the unusual case. I do not believe that we can say that the bleeding from peptic ulcer does not cause death. The complications of shock and the effects of prolonged loss of blood accounted for all but one of the deaths reported here. Deaths are not entirely confined to elderly patients; one of our fatalities occurred in a man 20 years of age.

HARD FACTS ABOUT PSYCHIATRY

C. CHARLES BURLINGAME, M.D.
Psychiatrist-in-Chief, the Neuro-Psychiatric Institute
HARTFORD, CONN.

I can understand the dismay that must have filled the heart of the old-time medical practitioner when, shortly after the World War as the new dynamic psychiatry—then a lusty infant with new, esoteric phrases and glib terminology—when, as I say, he came face to face with the new psychiatry for the first time! How his head must have whirled as he had the newly developed professional jargon thrown at him by some enthusiastic protagonist of the "new psychiatry." Because it was the World War that brought the so-called "new psychiatry" into prominence.

A psychiatric conference in those postwar strongly freudian days was an interesting and an awesome thing; new phrases, new words, new ideas were coined by each new adherent to the school of dynamic psychiatry. Conservative members of the profession were nearly engulfed in a sea of complexes, fixations, transferences and cross transferences, and they swam hopelessly against being engulfed in a veritable deluge of metaphysical and highly theoretical hypotheses.

So strong was this school of thought that it could not be held within the bounds of the medical profession but seeped over, adding salt—and perhaps a bit of salaciousness—to the drama, the arts, literature and even into the drawing room, where buxom ladies, bosoms billowing over tea cups, with a slightly self-conscious air, discussed the goings-on of their libido, their father fixation—"Electra" complex to you—and used words, which, in their more innocent days they would have thought obscene.

The dramatist O'Neil seized on it, and we learned of some of the strange, morbid undercurrents of the mind, through his *Strange Interlude*, *Mourning Becomes Electra*, and other productions. Lesser dramatists sensed the fact that there was gold "in them thar hills" and worked a rich tapestry of phallic symbolism into their work. Soon it was difficult to see anything but plays in which maladjusted individuals killed each other off in response to hidden urges or complexes having their roots in the dim, atavistic past, while novelists plied busy pens exposing, from another point of view, the miserable and degrading thoughts of men.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 19, 1939.

In short, for a period America was extremely self conscious, introverted, and the well informed freudian was fearful of even the slightest little mannerism, lest he betray to his colleagues, the fact that he was still a polymorphous pervert.

Those were happy days for some of the profession. It was before the depression and there were any quantity of neurotic, self-centered ladies and gentlemen who were willing to pay for the privilege of having the opportunity of talking about themselves and the state of their feelings in a dimly lighted room and to a sympathetic gentleman just lately returned from Vienna!

Small wonder that the general practitioner, the ophthalmologist, the pediatrician and the internist looked slightly aghast and made a mental note in confirmation of their previous estimate of psychiatrists and psychiatry.

But enough: I would not have you believe that I am belittling Freud or the remarkable contribution he has made to present day psychiatry. Rather, I have tried sketchily to point out the strange exotic atmosphere which prevailed in this country when Freud's teachings burst upon the public. Before Freud, psychiatry was static, hopeless and sterile. He breathed new life into it, and he gave us as we never had before an understanding of the human mind as a complex and dynamic thing. He destroyed in one brief year the artificial and highly dynamic structure of kraepelian definitive psychiatry, which was so concerned with disease labels that it did little about the disease itself.

But, much as we gained from Freud, there were losses too for a time. There was a loss because the ascendancy of the psyche over the soma resulted in an almost exclusive study of mental illness so called, from the psychogenic angle, and with consequent slowing up of other approaches.

There was a tremendous upswelling of interest in Freud's wake and with the usual results: the opportunist, the zealot, the quack and the scatterbrained seized on it—for sincere purposes in some instances, for exploitation in others. The more enthusiastic hailed it as a panacea for all human ills—the criminal was going to be reformed, the behavior problem was going to be eliminated, the psychotic was going to be restored to sanity. There was no claim too far reaching, too extravagant, and as a result the public was led to expect miracles.

Gradually, members of the medical profession began to look with even more skepticism than usual on this strange, scarcely acknowledged child of the medical family. They could not understand why some of its members, working in the name of science, should be so wholly lacking in scientific objectivity—so obviously moved by emotion rather than by reason. Psychiatry was then under the bar sinister in the family of medicine, and those who were in psychiatry, who weren't entirely satisfied to have the psyche run away with the soma, could do little but tend to their knitting.

And this modest tending to business, letting others save the world, this tending to knitting has begun to produce results, such results as make it possible for us to state here today that psychiatry does now take full account of both somatic and psychic disorders and that the real psychiatrist is aware more than ever before of the interdependence of the mind and the body. He realized that a sick body can make a sick mind or, conversely, that a sick mind can make a sick body.

Most physicians are aware of the signal advances made since the turn of the century in the field of psy-

chiatry. First there was Wagner von Jauregg's discovery of malarial therapy for dementia paralytica. Previously a variety of so-called disease entities, carefully labeled, were attributed to psychogenic causes; when malarial therapy was applied, however, it was discovered that the spirochete had various ways of manifesting its presence, depending on the type of personality of the sufferer and his constitutional predisposition, so that at one fell swoop a dozen different so-called mental diseases had a segment sliced off them.

It was a severe blow to the exclusively psychogenic school of thought!

We are aware of the mental symptoms associated with pellagra—and now we know that nicotinic acid will clear up these symptoms miraculously. We are aware of the symptomatology associated with an alcoholic psychosis which is really chronic poisoning, and the nutritional deficiencies manifest in neuritic disorders, now markedly influenced by vitamin therapy.

But the end was not there: workers in the field of electro-encephalography were adding still further proof to the rapidly accumulating evidence of the body's influence on the mind.

Gibbs, Davis, Lennox and other workers in the field of brain waves were building up a new conception of the human brain as a pulsing, dynamic thing, with a rhythm as constant and observable as the systole and diastole.

For the first time in medical history it was possible to record constitutional activities of the brain itself with as much clarity and accuracy as an electrocardiograph. Through the charting of these brain waves they discovered that the brain itself suffers from a dysrhythmia, a momentary spasm, in certain nervous disorders such as epilepsy, and that these dysfunctions could be recorded. For example, the rhythm was completely destroyed during an epileptic seizure. Psychogenic? Perhaps.

Within the past month Lennox and Gibbs have announced that carbon dioxide will influence the brain rhythm. If an epileptic patient pumps carbon dioxide from his lungs and blood by breathing hard, a seizure may result, and conversely, while he is breathing air which contains an increased concentration of carbon dioxide, petit mal ceases. It has been demonstrated that the electrical pattern of the brain is extremely sensitive to small changes in the carbon dioxide of the blood passing through it. Furthermore, there is every reason to believe that not only epilepsy but other forms of mental disorder may also be caused by a condition which produces a form of dysrhythm in the brain.

This relationship must, of course, be carefully worked out, but it would seem that here too the laboratory technician, the chemist and the careful physician who is basing his experiments on the foundation of good physical medicine are well on their way to making another valuable contribution.

There is reason to believe too that this line of experimentation is not too far removed from insulin and other shock therapy which produce anoxia or temporary nutritional deficiency in the brain, producing shock, which in turn has been found to be quite efficient in producing remissions in severe cases of mental disorder. There are some, of course, who state that the results of shock therapy are partly "psychological." But they do actually produce brain changes. What their precise mechanics is we are not yet prepared to

say, but their use as a therapy for the more severe psychoses has added still another weapon for the psychiatrist.

In this brief paper I can do little more than give a hint of some of the developments in psychiatry which are proceeding on good, solid ground. Important work is also being done in the field of endocrinology and allergy, and many are convinced that some forms of mental disorder can be traced to these sources.

But out of the entire field of developments emerges one significant fact, and that is psychiatry has come of age and is now working objectively, scientifically and with medical weapons to combat the biggest health problem in the country.

Even in psychotherapy there has been a radical revision of thought. Education and reeducation have become the keystone in all progressive hospitals, even though some may call it by other fancier names, and purposeful, constructive work of therapeutic value is being substituted for the old fashioned occupational therapy of yesterday. The patient now has a chance to leave the hospital possessed of training and with his field of interest broadened, his capacities for the enjoyment of life enlarged and his whole personality enriched by the training that has been given him.

But while considering these factors one must not lose sight of the other angle—that while the metaphysician and the psychogenist stand at one end of the axis, at the other end stands the stodgy organicist who believes nothing that he can't see under a microscope or that can't be extirpated with the surgeon's knife. No one will ever know how many neuroses have survived the removal of healthy gallbladders, removed by too materially minded surgeons, or how many appendixes have been removed, how many stomach ulcers treated, with no thought of the possibility of psychogenic background.

The work of Cannon in demonstrating psychosomatic relationships and the more recent work of Dunbar and others in showing the interrelationship of psyche and soma in many disease conditions must necessarily revise the old fashioned conception of disease as merely "disease tissue" and force a return to an earlier conception of the patient as a whole and not a collection of bone and various other tissue. We must be constantly aware that a stomach ulcer can be the end result of a psychic disturbance, just as we must realize that a psychic disturbance can be the result of a physical dysfunction or nutritional deficiency.

Happily the two ends of the axis are coming together. Soon, we hope, there will be no such thing as a psychogenic school and an organic school. The practicing physician will realize the importance of psychogenic factors and the psychiatrist will know the possible contribution of the various dysfunctions to a mental condition.

In fact, I think the day is coming when we shall stop talking about "mental disease" and "physical disease" because I am convinced it is an artificial and wrongful separation. The human organism becomes ill, and one cannot separate the human organism into separate entities any more than one can consider it apart from its environment. I say the distinction is an artificial one because it was thought that dementia paralytica was a "mental disease" and then was discovered to be caused by the spirochete. Does it now become a physical disease with mental symptoms? It may be demonstrated that there is scarcely a physical disorder that doesn't have its mental concomitants—a carbuncle on a patient's neck has a definite influence on his personality! More

difficult, perhaps, but just as logical is the assumption that there is no so-called mental disease that does not have its physical concomitants which may ultimately be demonstrated.

And when that artificial distinction between mental disease and physical disease is abolished in the minds of physicians generally it will be a good thing for psychiatry and it will be a good thing for the internist. Psychiatry can well profit by the painstaking laboratory research of physical medicine, and physical medicine can in turn ingest psychiatry with its leavening interpersonal relationship and its awareness of the psychogenic factors which are present in practically all disease conditions.

The modern psychiatrist should be on friendly terms with a stethoscope and at all times be a doctor. The men in other branches of medicine learn to know and use "psychological medicine."

Meanwhile, it would be well for general practitioners to realize that psychiatry has come out of its swaddling clothes and that it now stands mature, young to be sure, but with its wild oats behind, ready to assist by certain definite contributions to the art and the science of healing.

ABSTRACT OF DISCUSSION

DR. W. A. SAWYER, Rochester, N. Y.: I feel that we are coming to a period perhaps when not only industry but also public health and other spheres of preventive medicine are going to have to think about this subject of psychiatry in more general and practical terms. Psychiatry has been tried in industry in a number of places and, if it has failed, it has failed I think because the emphasis has been put too much on the matter of the specialty rather than on the principles involved and making them applicable to the practical, everyday medical work. The point that I tried to emphasize in my paper last week was the thought that you could infiltrate into an organization, even into the employment of individuals and personnel problems, the best psychiatric principles and you could accomplish a great deal in the adjusting of individuals to their jobs and helping them to understand the problems which confront them in their daily work. We are fortunate to have had as practical a paper as Dr. Burlingame has given us this morning.

DR. JOHN A. FERRELL, New York: May I ask Dr. Burlingame what those of us in public health work, interested from the community standpoint and also from the preventive standpoint, are keenly interested to know? What can be done in addition to the development of local health organizations that will make possible the finding of these cases in childhood that represent departures from the normal, and what might be done in the community within ordinary economic regions and the expansion of the health department to head these cases off if possible before they reach the institutional stage? What would you do in the matter of national and state public health nurses serving the community? Many of us admit we know nothing about it, and we don't know how to get at it.

DR. C. C. BURLINGAME, Hartford, Conn.: I am very glad to answer that question. I don't think the preventive work of psychiatry will ever be done exclusively by psychiatrists. I think a large part of it will have to be done by men in other branches of medicine and I further believe that much of the educational work that must be done to prevent the increase in mental and nervous diseases is going to be done through departments of health. There is frequently a strange isolation between the mental hospital and the departments of mental hygiene on the one hand and the public and the general practitioner on the other hand. It is unfortunate that some departments of mental hygiene are so remote from the men who are practicing medicine. I have come to the conclusion that there is no more reason for separating the preventive work in psychiatry than there is for separating the work being done in preventing contagious diseases. I think they should go under the same general leadership, and in that way we shall get at the rank and file

of men practicing medicine. Usually, now when a patient gets to the psychiatrist the situation is pretty well developed. I am opposed to the development of great, powerful departments of psychiatry in state organizations or in medical schools, if such development prevents the free infiltration of psychiatric principles into all other branches of medicine. In fact, I am opposed to anything which would tend to isolate psychiatry from the general practice of medicine. As to how to prevent mental disease, that is what you gentlemen will have to tell us. We have talked about preventing mental disease for many years but we are still building bigger and better state hospitals and the only change that has really taken place in some of them is that their name has been changed from "asylum" to "hospital." I should like to see the intellectual walls of the state hospital torn down. I should like to see the doors open. And if you send your patient to the state hospital I see no reason why you shouldn't follow his progress in the hospital. In fact, if you will not come to the hospital of your own volition, I think you should be dragged there. You, the members of other branches of medicine, can do a great deal toward breaking up these isolated systems that now sometimes exist within our state hospitals. I think the first step is a closer rapport between the state hospitals and the general practitioner, through the destruction of the state hospital's all too frequent isolation.

CLINICAL AND EXPERIMENTAL STUDIES ON VITAMIN K

H. P. SMITH, M.D.

AND

G. R. HOFFMAN, M.D.

IOWA CITY

It is our purpose in the present paper to discuss the bleeding tendency so often seen in patients having biliary fistulas or obstructive jaundice. In many of these patients death occurs from persistent hemorrhage. This hemorrhage may begin independently of known trauma, but usually it begins at operation or appears from the wound after operation. It is now known that the bleeding is due to abnormal lowering of the plasma prothrombin level and that in most cases the bleeding tendency can be relieved by vitamin K therapy. We wish to outline the experimental and clinical work on which this theory is based, and along with this we wish to describe, briefly, a simple method that we have recently devised for the recognition of the vitamin deficiency. With the aid of this test it is now possible to obtain information at the bedside regarding vitamin K requirements. It is also a simple matter to determine, from time to time, the effect obtained from vitamin K already given.

HISTORICAL SKETCH

The existence of vitamin K was first suspected from experiments done nine years ago by Dam² of Copenhagen. In some studies on lipoid metabolism, newly hatched chicks were placed on a fat-free diet. After several weeks these chicks developed hemorrhages into

the skin, mucous membranes and other portions of the body. This work prompted further study, and it was demonstrated that a new fat-soluble vitamin is essential for the prevention of this bleeding tendency. The Danish word for "coagulation" resembles the German word and is spelled "koagulation." The vitamin was therefore spoken of as "vitamin K."

Subsequent studies by Dam and his colleagues³ and by others,⁴ notably by Almquist of California, showed that: (a) Vitamin K is present in large amounts in certain green vegetables such as alfalfa, spinach and kale. The vitamin is a colorless compound, however. (b) The vitamin can be produced by bacterial action and is therefore present in the lower portion of the intestine, even when the animal is maintained on a diet free of the vitamin. Absorption from the lower part of the intestine is minimal in the chick, but in mammals absorption does occur and hence mammals rarely show vitamin K deficiency⁵ except in cases of faulty absorption. (c) By rather elaborate chemical technic it has been possible to isolate the vitamin in the form of a highly potent oil. The chemical composition of the oil is not known, and reports⁶ indicate success in obtaining this compound in crystalline form. (d) In chicks maintained on a diet free of vitamin K it was found that the prothrombin level was low, and this explained the bleeding. It has not yet been determined whether vitamin K enters chemically into the formation of prothrombin or whether the vitamin merely keeps certain tissues in a normal healthy state of activity essential for the formation of prothrombin.

As has been stated, mammals, including man, obtain vitamin K both from the diet and from bacterial activity in the intestine. A vitamin K deficiency develops when absorption of this particular compound from the intestine is interrupted. Faulty absorption occurs when bile is excluded from the intestine. Bile has long been known to aid in the absorption of fats. Vitamin K is a compound having the solubility properties of fats, and without bile or bile salt it cannot be absorbed. In obstructive jaundice or in patients with biliary fistulas the intestine receives no bile and hence the absorption of vitamin K is interrupted. After a few weeks or months the plasma prothrombin level falls and a tendency to bleed develops.

Treatment consists in feeding bile or bile salt, along with large amounts of vitamin K, to supplement the natural supply. This use of vitamin K in obstructive jaundice was first proposed on theoretical grounds by Quick,⁷ though he made no direct tests to prove the

validity of his proposal. In fact, in one case, which he⁸ reported later, a patient on vitamin K therapy failed for some reason to respond.

Historically, the first direct evidence reported in support of the new theory was supplied by Greaves and Schmidt.⁹ They showed that in rats with biliary fistulas a prothrombin deficiency develops, thus confirming similar observations of Quick, Stanley-Brown and Bancroft¹⁰ made in human cases of obstructive jaundice, and of Hawkins and Brinkhous¹¹ in dogs with biliary fistulas. They also found that this deficiency could be relieved by feeding vitamin K and bile salt. Two months later the first successful treatment of human patients was reported from our own laboratory,¹² and our report was followed immediately by a report of similar results obtained by Butt, Snell and Osterberg¹³ at the Mayo Clinic. Since that time confirmatory evidence has been supplied by Dam and Glavind,¹⁴ our laboratory,¹⁵ the workers at the Mayo Clinic,¹⁶ Olson,¹⁷ Stewart¹⁸ and Rhoades.¹⁹

Recent work from this laboratory²⁰ has shown that the liver is concerned in the manufacture of prothrombin. When the liver is partially excised or is injured by poisons, infection or tumor growth, the level of plasma prothrombin falls. In these cases there is no vitamin deficiency, and feeding vitamin K does not cure the condition.

DETECTION OF VITAMIN K DEFICIENCY

Vitamin K deficiency is to be suspected in all cases in which there are biliary fistulas or obstructive jaundice. The degree of deficiency tends to be greatest in cases of long duration but is sometimes marked when obstruction is of recent origin (from two to three weeks). If a deficiency does exist, it is important that the patient receive vitamin K therapy for several days before any operative procedures are undertaken. Any attempt to treat all suspected cases as a routine will

result in needless delay in those cases in which vitamin K deficiency is not yet present. The ordinary tests for bleeding and clotting time reveal the abnormality only when the prothrombin deficiency is extreme. They give normal values when the plasma prothrombin level is merely approaching the danger zone. These tests, therefore, fail when they are most badly needed. The two stage technic for the titration of prothrombin developed in this laboratory²¹ gives the most exact measure of the vitamin deficiency yet devised, and for purposes of research this technic is to be recommended. However, the method is too complex for routine clinical use. The one stage method of Quick²² is less specific as a test for prothrombin but it is simpler from a technical standpoint. Even so, it requires the collection of blood in oxalate, the use of the centrifuge and finally a titration procedure. A test which we have recently devised¹ is similar in principle to the test of Quick but is carried out on whole blood at the bedside and is so simple that it can be mastered with very little practice.

A New Test for Vitamin K Deficiency.—With a serologic pipet, 0.1 cc. of thromboplastin, described in the next paragraph, is placed in a small serologic tube (75 by 10 mm. outside diameter). In the tube is then placed blood, freshly drawn from the patient, up to a 1 cc. mark previously made on the side of the tube. The tube is at once inverted over the finger to obtain complete mixing of the blood and thromboplastin. The tube is tilted every second or two in order to observe clotting. As a control, the test is also carried out on the blood of a normal subject. The calculation is as follows:

$$\text{Clotting activity (in percentage of normal)} = \frac{\text{Clotting time of normal control}}{\text{Clotting time of patient's blood}} \times 100$$

Thus, if the patient's blood clotted in forty-eight seconds and the normal person's blood in twenty-four seconds, the clotting activity is calculated to be 50 per cent of normal.^{22a}

To prepare thromboplastin, fresh lung of ox or rabbit is ground, and to each 10 Gm. portion is added 10 cc. of physiologic solution (0.9 per cent) of sodium chloride. This is stirred at intervals for several hours. The fluid then obtained by straining through gauze is the "thromboplastin" employed in the test described. This thromboplastin keeps well in the ice box.

Interpretation of Results Obtained with the Test.—The new test is not as specific for prothrombin as the two stage method²¹ that we use for purposes of exact research. However, the new test, like that of Quick,²² is a presumptive measure of the amount of prothrombin present in the plasma. Work from this laboratory²³ has shown that other factors do influence the reading. Thus, in some cases the prothrombin is more easily converted than in others, and this compensates for a deficiency in the amount of prothrombin. The new test, like that of Quick, measures a summation of the amount of prothrombin and of its "convertibility." One thus obtains a very practical measure of the tendency to bleed. Experience with a large group of

patients having biliary fistulas or obstructive jaundice shows that bleeding commonly occurs when the test gives values of 40 per cent or less. In extreme cases, the level falls as low as 15 per cent of normal. Values of from 40 to 70 per cent are definitely in the danger zone.

THERAPEUTIC USE OF VITAMIN K

Vitamin K is readily obtained in crude form by the extraction of alfalfa meal with high-test gasoline (free of lead). The gasoline is removed by distillation, and the crude vitamin is emulsified in bile or in a 2 per cent solution of bile salt. The vitamin can be purified by a variety of chemical procedures, and recently a number of drug firms have undertaken to prepare the vitamin in a form suitable for clinical use. One of these preparations,²⁴ in capsule form and dissolved in oil, is already on the market. Another,²⁵ a cereal grass preparation, is supplied in powdered form. Preliminary work indicates that under certain conditions the vitamin keeps

Curve of postoperative fall in prothrombin in obstructive jaundice. Rapid recovery following administration of vitamin K and bile salts. Note close correspondence between prothrombin by old (two stage) method and by the new simplified test.

well at room temperature, but evidence²⁶ indicates that this is not true under all conditions.

Much is still to be learned about the amount of vitamin K to be administered. Some vitamin K is formed by intestinal bacteria and some is present normally in the diet; hence the daily feeding of bile prevents the fall in prothrombin incident to biliary fistula.¹¹ Feeding bile also restores the prothrombin level to normal in cases in which it has already fallen to low levels.²⁷ However, the recovery in such cases is slow unless the diet is artificially enriched with the vitamin. To obtain a rapid rise in the prothrombin level we make it a practice to administer daily the vitamin K extracted from 300-400 Gm. of alfalfa meal. Vitamin K assay technic is not well enough standardized to permit accurate comparison of the various products used in different clinics.

Evidence now at hand indicates, however, that the dosage we employ is much larger than that used by certain other workers in this field and is possibly smaller than that used in some clinics. It is very important that methods of vitamin K assay be improved and standardized and the keeping qualities of the vitamin be carefully determined and controlled. When this is done, the question of clinical dosage will be more easily studied.

In treating patients bile or bile salt must be fed along with the vitamin to aid in the absorption of the latter from the intestine. It is customary to feed daily at least an ounce of bile or its equivalent in the form of dried bile or bile salt. We have recently had two cases which failed to respond on this dosage when given along with the usual dose of vitamin K. They did respond, however, when the dose of bile was increased five fold, the dose of vitamin K being unchanged. It is probable that some patients require more bile than others; also that some require more vitamin K than others. Evidence now available indicates that bile salt may be as effective as whole bile, but further work is needed in regard to this.

The rate at which the plasma prothrombin level rises with vitamin K therapy varies in different cases. As a rule a definite rise occurs in twenty-four hours, but from three to eight days of treatment is usually needed to obtain the maximal response.

It cannot be emphasized too strongly that the vitamin treatment should be continued during the postoperative period,²⁸ especially if bile continues to drain from the wound. In addition to the lack of vitamin, such patients no doubt consume prothrombin in large amounts in forming fibrinous exudate in the margins of the wound. In all cases the clotting test, already described, should be performed every few days during the postoperative period in order to guard against a disastrous fall in prothrombin.

Finally, it need hardly be mentioned that vitamin K is of no value in the treatment of hemophilia or thrombocytopenic purpura. In these diseases there is no deficiency in vitamin K and no deficiency in prothrombin. Nor can one expect a response to the low prothrombin levels often present in cirrhosis of the liver or in cases of severe hepatitis. In these cases the "factory" that forms prothrombin is disordered, and the disease is not essentially one of vitamin K deficiency.

AN ILLUSTRATIVE CASE OF VITAMIN K DEFICIENCY

A white man aged 70 entered the hospital with the complaint of painless jaundice of two months' duration. The stools were clay colored and the urine was a dark yellow. Intense pruritus was present, and the patient had lost 10 pounds (4.5 Kg.). The gallbladder could be felt on palpation. Operation, performed by Dr. F. J. Jarvis, showed inoperable carcinoma of the ampulla of Vater. A stone was removed from the gallbladder. Cholecystogastrostomy was performed and the wound was closed without drainage.

Prior to operation the bedside clotting test on two occasions gave values of 78 and 62 per cent of normal. This was not considered in the danger zone, and vitamin K (from 300 Gm. alfalfa) and bile salt (30 cc. of 2 per cent solution) were given for two days only, without any well marked effect. (It has been our experience that patients in this zone are less likely to respond promptly than when the prothrombin lowering is more pronounced.)

Vitamin K therapy was discontinued following operation, and on the sixth postoperative day blood began to ooze in large

amounts from the wound. The bedside clotting test was 22 per cent of normal. Vitamin K and bile salt therapy was resumed and within two days the bleeding ceased and within five days the level had risen to 95 per cent of normal.

In this same case prothrombin determinations were also made by our two stage method, which is more specific for prothrombin. The excellent correlation with the bedside test is shown in the accompanying chart. For practical routine clinical use we are confident that the new test fulfils all essential requirements.

NOTE.—Since this paper was written, Almquist and Klose²⁹ have shown in chicks that phthiocol, a yellow compound prepared synthetically by R. J. Anderson, has vitamin K activity. Immediately thereafter work from that and other laboratories³⁰ showed that vitamin K activity was possessed by a number of other naphthoquinones.

With the aid of Dr. Joseph E. Flynn we have recently had success in the use of phthiocol intravenously in cases of obstructive jaundice. In one case, 45 cc. of 0.2 per cent solution in isotonic phosphate buffer (pH 7.4), given in divided doses, raised the prothrombin from the 39 to the 75 per cent level in twenty-four hours. No toxic effect was observed. We are indebted to Dr. Anderson for the phthiocol used.

THE PREOPERATIVE AND POST- OPERATIVE ADMINISTRATION OF VITAMIN K

TO PATIENTS HAVING JAUNDICE

HUGH R. BUTT, M.D.

ALBERT M. SNELL, M.D.

AND

ARNOLD E. OSTERBERG, Ph.D.

ROCHESTER, MINN.

Studies on the factors concerned in the production of hemorrhagic diathesis characterizing patients who have jaundice have been discussed in previous papers.¹ Numerous other investigators have demonstrated definitely that cholemic bleeding is caused by a deficiency of prothrombin in the circulating blood and that both this deficiency and the hemorrhagic state associated with it can be corrected by the administration of concentrates containing the fat-soluble antihemorrhagic vitamin K, together with bile salts to insure absorption of the vitamin. The early clinical application of this knowledge concerning vitamin K was begun independently in the United States by Warner and his associates² at the University of Iowa and by us, and abroad by Dam and his co-worker³ in Copenhagen.

During the past two years we have continued our observations on this problem, several lines of investi-

gation having been pursued. We have endeavored to determine the reliability of vitamin K concentrates in the control of bleeding of jaundiced patients and also to establish standardized methods of the preoperative and postoperative treatment of such patients. An investigation of the causes of failure among occasional patients who do not respond to the administration of vitamin K by an increase in the prothrombin content of blood and control of the hemorrhagic state also has been carried out. Finally, we have attempted to study other causes for a deficiency in the content of prothrombin, a matter which is concerned chiefly with defects in the absorption of this material. These studies constitute the basis of the present report.

THE CLINICAL PROBLEM OF CHOLEMIC BLEEDING

The earliest reported case of fatal bleeding in a patient having jaundice was made by Wedelius⁴ in 1683. Since the advent of listerian surgical technic, the tendency to bleed which is peculiar to patients having jaundice has been a factor of grave concern to the surgeon. In the early reports by Musser and Keen,⁵ Depage,⁶ Greig Smith⁷ and Mayo Robson,⁸ hemorrhage accounted for a large part of the high mortality that accompanied the surgical treatment of the jaundiced patient. Even current figures indicate that cholemic bleeding has accounted for about 50 per cent of the mortality accompanying surgical intervention on patients having jaundice and that cholemic bleeding, of itself, imposes a surgical risk of approximately 5 per cent.

There is now general agreement that hemorrhagic diathesis in the presence of jaundice is not the result of any alteration in the amounts present of calcium, bilirubin, platelets, fibrinogen or thromboplastin. The original suggestion of Quick and his co-workers⁹ that the condition depended on a lack of the one substance necessary for coagulation not previously studied, namely prothrombin, has now been amply confirmed. Evidence has also accumulated to prove that a particular fat-soluble material (that is, vitamin K) normally present in the intestinal tract, is absorbed and utilized by the liver in some unknown manner to maintain a normal concentration of prothrombin in the blood plasma.

The composition of prothrombin is unknown; it may well be defined, as suggested by Patek and Taylor,¹⁰ as a physiologic complex known only by its capacity to form thrombin. For this reason, any method for measuring the content of prothrombin in the circulating blood must be considered an indirect one.

Concerning the mechanism by means of which vitamin K affects prothrombin we have no data and, until vitamin K is isolated in pure form, this phase of its physiologic activity probably will remain unanswered.

The recent report by Almquist and Klose¹¹ offers hope that pure vitamin K will soon be available.

For routine determinations of the content of prothrombin we have used the method of determining the prothrombin coagulation time as developed by Quick and his associates⁹ and have found it well adapted for general laboratory use. In many instances we have also employed the quantitative method of study of blood

Chart 1.—The effects of the parenteral administration of vitamin K concentrates on the prothrombin clotting time and the quantitative content of prothrombin in plasma, of a patient having stricture of the common bile duct.

clotting of Warner and his associates.² When “prothrombin time” or “prothrombin clotting time” is used subsequently it refers to the clotting time of recalcified plasma to which optimal amounts of thromboplastin have been added as determined by the method of Quick. The normal time varies between eighteen and twenty-four seconds, depending on the activity of the thromboplastic material employed.

THE VITAMIN USED: ITS POTENCY

Vitamin K is perhaps best defined as a fat-soluble substance a deficiency of which in the diet of young chicks results in an abnormal tendency of these animals to bleed. Its exact chemical composition is unknown and the only available preparations for clinical use represent nothing but biologically tested concentrates of this antihemorrhagic material and perhaps other substances.

In our^{1a} earlier experiments, concentrates of vitamin K prepared from putrefied fish meal were used. These were effective in the prevention and control of cholemic bleeding. The material used during the past one and a half years was prepared in cooperation with the Abbott Laboratories from alfalfa meal extracted with petroleum ether; from the final product, chlorophyll and certain other pigments have been removed by adsorption. The preparations have a potency of 20 mg. or less per kilogram of chick diet as measured by Dann's modification¹² of the Almquist method. Two hundred mg. of the crude concentrate was approximately equivalent to 66 Gm. of dry alfalfa meal and was estimated to contain about 37,500 Dam units. These measures of unit value are obviously of limited value and cannot be evaluated properly until vitamin K has been isolated in pure form.

DOSAGE AND METHODS OF ADMINISTRATION OF VITAMIN K

The minimal requirements and exact dosage of vitamin K necessary for the control of the hemorrhagic diathesis of jaundiced patients must await the further chemical purification and isolation of vitamin K. Eventually, these considerations will doubtless depend on the duration of jaundice, the degree of hepatic injury and the state of hypovitaminosis present.

Oral Administration.—Depending on the individual patient, the daily dosage has varied from 200 mg. to 8 Gm. of the crude concentrate. As much as 20 Gm. of the latter material has been administered by mouth for a period of seven days without the appearance of any untoward reactions; 13 Gm. of the crude concentrate mixed in peanut oil has been administered intramuscularly for a period of four days without harmful effects.

For purposes of routine preoperative treatment, we have divided our jaundiced patients into three groups: (1) those who have a normal prothrombin time, (2) those who have a prolonged prothrombin clotting time without active bleeding and (3) those who have a prolonged prothrombin clotting time with active bleeding.

Those jaundiced patients of the first group who have a normal prothrombin time have nevertheless been administered prophylactic treatment for from two to five days before surgical intervention is undertaken. From two to six gelatin capsules (each capsule containing approximately 200 mg. of alfalfa concentrate), together with from 1 to 4 Gm. of animal bile salts, seems to constitute an adequate daily dose. Almost any type of animal bile salts can be used, but we have preferred water-soluble bile salts, particularly in those instances wherein concentrates of vitamin K must be administered by means of a duodenal tube or T tube. Human bile obtained from a biliary fistula or a T tube as previously described by us^{1a} or lyophilized bile as described by Johnston¹³ may also be employed.

Those patients having jaundice who have an elevated prothrombin time constitute a potential or real emergency and have been treated as such. Most patients having a prothrombin time of from thirty to forty-five seconds will respond well to the plan of prophylactic treatment previously mentioned, but if the prothrombin time is longer than

forty-five or fifty seconds it has been thought advisable to administer concentrates of the vitamin together with bile salts either by duodenal tube or through a T tube. In such instances from 2 to 4 Gm. of a water-soluble bile salt is dissolved in from 250 to 500 cc. of warm

13. Johnston, C. G.: Preoperative and Postoperative Treatment in Cases of Obstructive Jaundice, *Surgery* **3**: 875-883 (June) 1938.

Chart 2.—The effects of vitamin K concentrates alone and in combination with bile on the prothrombin clotting time of a patient suffering from complete acholia, taking no food by mouth. Note that no effect was obtained until bile was administered.

physiologic solution of sodium chloride or tap water; to this is added from 1 to 2 Gm. of the concentrate of alfalfa containing vitamin K. The mixture is shaken thoroughly and administered slowly in from thirty to sixty minutes by the drip method; care is taken to keep the solution warm and well mixed. One such dose, as a rule, will bring the prothrombin clotting time to a normal value. In the exceptional instance it has been necessary to repeat this procedure one or more times.

Chart 3.—The effect of human bile obtained from a biliary fistula on the prothrombin clotting time of a patient who was ingesting an adequate diet.

When large or repeated doses are used, the prothrombin time usually decreases within six to twelve hours.

The problem of treatment of patients who are actively bleeding is difficult. Clotted blood must be removed by lavage before adequate absorption of the vitamin can occur, and

not infrequently gastric lavage and irrigation of drainage tubes leading from the biliary tract are required. A transfusion of blood often is necessary to aid in combating the shock produced by hemorrhage and to provide a temporary supply of prothrombin; a transfusion will as a rule control bleeding only so long as the added supply of prothrombin lasts, a matter of from six to twelve hours. Rhoads and Panzer¹⁴ suggest that "bank blood" is low in prothrombin and is therefore of little value in controlling hemorrhage in these cases. Treatment with the vitamin concentrate and bile salts is carried out in the meantime as described in the preceding paragraph and repeated as necessary.

Intramuscular Use of Vitamin K.—Parenteral administration of vitamin K has been used by Dam and Glavind¹⁵ for a total of eight patients having obstructive jaundice. Emulsions of concentrates of alfalfa containing vitamin K were administered by the intramuscular route; such injections were followed by a diminution in the elevated R¹⁶ values (coagulation times) in their patients. The responses obtained were not conspicuous until from five to seven days had elapsed. Similar results were obtained in chickens with elevated R values produced by ligation of the choledochus following a single intracardial injection of vitamin K concentrate. Greaves¹⁷ has found concentrates of vitamin K to be effective in the rat when administered either subcutaneously or intraperitoneally.

We have administered intramuscularly to patients concentrates of alfalfa containing vitamin K mixed with peanut oil; this has been given in single doses varying from 200 to 3,200 mg. of the crude concentrate. There was little immediate change in the elevated prothrombin time following the daily injection of amounts up to 2,000 mg. The most satisfactory response was obtained in the treatment of a patient having a stricture of the common bile duct of two and one-half years' duration.

A total of 3.2 Gm. of crude concentrate mixed with peanut oil was given intramuscularly on four successive days. The effect on the prothrombin time is shown in chart 1. We have had a few patients whose elevated prothrombin times have decreased following the intramuscular injection of vitamin K, but in the main the effects have not been striking.

THE ABSORPTION OF VITAMIN K FROM THE DIGESTIVE TRACT

The Influence of Bile on Absorption.—It was demonstrated early that concentrates of fish meal, together with bile salts, were effective in controlling the hemorrhagic diathesis of patients having jaundice; the next consideration was to determine the effect on this condition of vitamin K and bile salts administered separately. Results of this investigation have been reported previously by us.¹⁸ We administered daily doses of 200 mg. of fish meal concentrates for seven days to a patient who had complete acholia and who was taking no food by mouth. No effect was noted and the prothrombin time continued to rise; it dropped rapidly, however, following the administration of bile and vitamin K together (chart 2). This result illustrates clearly the failure of absorption of the fat-soluble antihemorrhagic material when bile is absent from the intestine. This observation has been confirmed by the experimental work of Greaves and Schmidt¹⁸ and of Heymann,¹⁹ who have demonstrated independently the importance of bile in the absorption of other fat-soluble vitamins from the intestinal tract.

The remaining consideration was to determine the effect on the prothrombin time of bile alone. It has previously been shown that normal and acholic feces have a definite protective effect on K-avitaminous chicks, indicating that the vitamin is normally present in the intestine (Butt and Osterberg²⁰). A patient who was ingesting an adequate diet was given 250 cc. of fresh human bile obtained from a biliary fistula; within twenty-four hours the elevated prothrombin time had decreased to a near normal figure (chart 3). Similar results have been obtained independently by Warner and his associates.²

These clinical experiments have been confirmed recently in the experimental laboratory. Greaves²¹ has demonstrated that bile is essential to the absorption of vitamin K by the rat and that, in animals subsisting on a K-deficient diet, bile alone has no effect on the hemorrhagic tendency, whereas vitamin K plus bile salts is immediately effective.

The Importance of a Normal Intestinal Surface for Absorption.—It is obvious that normal absorption of a fat-soluble material from the intestine cannot take place unless an adequate and physiologically intact intestinal surface is available. That deficiency in the concentration of prothrombin can develop because of disease of the intestinal tract has not hitherto been demonstrated, so far as we are aware. Recently we have had the opportunity of observing a group of patients suffering from K-avitaminosis which resulted apparently from an inadequate intake of food, abnormal or insufficient intestinal absorptive surface, or both.

REPORT OF CASES

CASE 1.—A markedly debilitated male patient who had chronic ulcerative colitis and who presented other evidence of nutritional deficiency underwent resection of the colon; several days later the patient was found to be bleeding freely from a tube which had been inserted into the small intestine. The prothrombin clotting time was forty-six seconds. Concentrates containing vitamin K were administered at once by way of the enterostomy and on the following day the bleeding ceased. The prothrombin time had decreased to twenty-six seconds.

CASE 2.—A boy suffering from multiple polypi of the transverse and descending colon and rectum had suffered from multiple attacks of intestinal obstruction with resulting loss in weight and strength. Excision of the left half of the transverse and descending colon had been performed following preliminary ileosigmoidostomy. Shortly thereafter partial intestinal obstruction developed, which persisted for a period of twenty-eight days; there was an intervening period of three days during which the obstruction was spontaneously relieved. After unsuccessful attempts to relieve the obstruction by intestinal intubation, enterostomy was finally done. Forty-eight hours later, blood began to drain freely from a tube which had been inserted into the small intestine. The prothrombin time was found to be greatly prolonged (151 seconds). Vitamin K concentrates and bile salts were administered through the enteric stoma, resulting in an immediate decrease in the prothrombin time to the normal value, cessation of bleeding and eventual recovery.

CASES 3 and 4.—Two cases of chronic ulcerative colitis were studied. The first patient, who had a high iliac stoma, had a prothrombin level of 67 per cent (as measured by the method of Warner). There had been no bleeding other than that associated with the primary disease. The second patient was bleeding freely from the enteric stoma and the prothrombin clotting time was forty-four seconds. Bleeding was controlled for this patient by the administration of concentrates of vitamin K and bile salts, and the prothrombin time decreased to twenty-four seconds.

CASE 5.—A male patient having a gastrojejunal fistula of two years' duration had on admission a prothrombin clotting time of sixty seconds; a quantitative estimation of prothrombin produced low values (9 to 12 per cent). No bleeding had occurred at any time. Combined intramuscular and oral administration of vitamin K concentrates corrected the deficiency in prothrombin; the prothrombin time decreased to thirty seconds and the quantitative content increased to 48 per cent.

CASES 6 and 7.—Two cases of nontropical sprue were studied. The first patient had a content of fat in the stools of 40 per cent (dry weight). The fat content of the stools of the second patient was 33 per cent (dry weight). The level of prothrombin in the circulating blood as measured by the method of Warner

was definitely reduced (47 per cent and 62 per cent of normal, respectively). No hemorrhagic tendencies had been noted as afflicting either patient. Fatal hemorrhagic diathesis may occur in the presence of sprue; the occurrence probably depends on K-avitaminosis and prothrombin deficiency. Fanconi²² recently has reported that in the presence of celiac disease of children there is, because of the abnormal absorption of fat, an abnormal tendency to bleed. He noted the existence of hypoprothrombinemia in such cases and a prolonged coagulation; he has suggested that this "skorbutoid" tendency might be caused by a deficiency of vitamin K. Engel²³ has made a similar suggestion.

TABLE 2.—Effect of Preoperative and Postoperative Administration of Vitamin K in 127 Cases of Jaundice *

* Sixty-four of these cases have been reported previously.

While cases of prothrombin deficiency referable to defects in intestinal absorption are not often encountered, they do comprise a rather distinct group and one which bears further investigation. When hemorrhage of patients having extensive disease of the intestine occurs either before or after surgical treatment, deficiency in prothrombin should be excluded before other forms of treatment are instituted. The optimal site of absorption of vitamin K in the intestinal tract is not as yet known; Dixon and Clark²⁴ at the Mayo Clinic are now investigating the problem. The material is taken up rapidly from the jejunum, as has been previously mentioned, but it does not seem to be absorbed from the stomach or colon.

THE ROLE OF THE LIVER IN THE UTILIZATION OF VITAMIN K

In the preceding paragraphs the presence of bile in the bowel and a normal intestinal surface are proved to be of importance in the absorption of vitamin K and in maintaining a normal concentration of prothrombin. An equally important factor, the integrity of the hepatic parenchyma, remains to be considered. The liver is assumed to be the site of formation of prothrombin, as indicated by the studies of Smith and his associates.²⁵ They demonstrated the important role of this organ in the formation of prothrombin in their studies on dogs suffering from intoxication with chloroform. If hypoprothrombinemia is accepted as being the principal factor responsible for the hemorrhagic tendency of patients having jaundice, it may reasonably be assumed that in many such instances the element of hepatic parenchymal damage has a distinct bearing on the condition. Actually, even a badly damaged liver is capable of synthesizing prothrombin; we have records of patients who presented every known clinical evidence of hepatic insufficiency and who have exhibited maximal degrees of physiologic disturbance (as determined by studies of

hepatic function) who have been able to absorb and utilize vitamin K and maintain normal values for the concentration of prothrombin in the blood. However, within the past year we have encountered, as has Warner,²⁶ certain patients having severe hepatic damage who did not present the usual prompt response in prothrombin clotting time following the administration of vitamin K. In one instance the patient showed no response whatever.

RESULTS OF VITAMIN K AND BILE SALT THERAPY

Concentrates of vitamin K prepared from alfalfa, together with animal bile salts, have been administered to 127 patients suffering from jaundice of various types who were subjected to various surgical procedures; ninety-five (75 per cent) of these had obstructive jaundice subsequently. Sixty-four of the cases represented by these 127 patients have been reported previously.¹⁰ The diagnoses for these 127 patients and the number of patients in each diagnostic group who bled are presented in table 1. The frequency with which the hemorrhagic state develops in these patients is apparent.

For a large majority of these patients, bleeding has been adequately controlled by the administration of concentrate of vitamin K and bile salts; typical responses are illustrated in charts 5 and 6. There are some patients for whom this treatment must be regarded as a failure, a matter which will be discussed subsequently.

Chart 5.—The effect of a surgical procedure on the prothrombin clotting time; actual bleeding was controlled and a greatly prolonged prothrombin clotting time was reduced to normal by the administration of vitamin K concentrates and bile salts.

occasions but little surprise. In this series the bleeding of patients having carcinomatous obstruction as a rule was recognized early and was adequately treated. Unfortunately, relatively little attention has been paid to the danger of the postoperative bleeding of patients who have gallstones and hepatitis. As a result, there were numerous unexpected episodes of hemorrhage in this group of patients.

26. Warner, E. D., in discussion on Butt, H. R.; Snell, A. M., and Osterberg, A. E.: Oral and Intramuscular Administration of Vitamin K in Hemorrhagic Diathesis of Obstructive Jaundice, *abstr. J. A. M. A.* 112: 879-880 (March 4) 1939.

We have learned that a normal prothrombin clotting time on the day of operation does not guarantee the nonoccurrence of postoperative bleeding and that close attention to the risk of hemorrhage is warranted in the treatment of all patients who have obstructive jaundice and hepatic damage arising from whatever cause.

In the hepatic parenchyma of a number of patients suffering from advanced cholecystic disease, the surgeon at operation observes various gross changes. The finding of moderate or severe hepatitis in such instances

Chart 6.—The effect of vitamin K concentrates when injected intramuscularly and by duodenal tube on a prolonged prothrombin clotting time.

should constitute a warning that added precaution during the postoperative period is necessary. The integrity of the hepatic parenchyma may be a controlling factor in such instances, and because of this fact the importance of continuing all known methods of maintaining and improving hepatic function in patients having jaundice or hepatic injury cannot be overemphasized. The ready availability of vitamin K should not lull either the clinician or the surgeon into any false sense of security; the material should be employed in conjunction with other methods which are known to be of value in the restoration of normal hepatic function.

THE VALUE OF PREOPERATIVE TREATMENT

The value of the preoperative administration of vitamin K is well illustrated by an analysis of the sixty-three recently studied cases mentioned in an earlier paragraph. Of eight patients to whom no concentrate of vitamin K or bile salts was given before surgical intervention, bleeding occurred postoperatively in five (63 per cent). This incidence of bleeding is about sixteen times greater than the incidence of postoperative bleeding in the group of forty-five patients to whom concentrates of vitamin K and bile salts were given both before and after surgical intervention; of the two patients (4 per cent) of this group who bled, one had only a slight oozing of blood from the T tube and the other patient had pyloric obstruction of a degree which precluded successful treatment. Vitamin K concentrates

and bile salts were administered to ten patients before but not after operative procedures. Only one patient bled to a serious extent, and this patient had received inadequate amounts of vitamin K before surgical treatment. The analysis of these sixty-three recently studied cases is very similar to that of the group previously reported by us; figures for the combined groups are represented in table 2. The importance of preventive or preoperative measures in the treatment of this group of patients is paramount and, as Elvehjem has stated in another connection, the time to treat deficiency states most advantageously is that at which they are detectable by laboratory means rather than that at which clinical symptoms are apparent.

CLINICAL INTERPRETATION AND USE OF THE PROTHROMBIN CLOTTING TIME BEFORE AND AFTER SURGERY

It must be assumed that present methods for measuring the content of prothrombin in the circulating blood are subject to considerable error. These methods are indirect and, as may be said of many other helpful laboratory procedures, they do not always produce all the information desired. We have observed what we

believed to be cholemic bleeding afflicting two patients having normal prothrombin times; in each instance the bleeding was controlled by the administration of vitamin K. In all other instances wherein cholemic bleeding occurred, the prothrombin clotting time was at least twice the normal value or higher; however, we have notes of several patients who had a prothrombin time of from sixty to ninety seconds, yet these patients exhibited no gross evidence of bleeding. The decrease in the concentration of prothrombin in the circulating blood necessary to produce bleeding in man seems to depend on certain unknown individual factors; it certainly bears no constant relationship to the type of hepatic or biliary disease present. Very rapid changes in the coagulating properties of blood have been repeatedly noted in this series of patients.

The prothrombin time of patients having jaundice usually increases to some extent for the first three or four days after surgical operation, but it may increase rapidly even as late as the eighteenth postoperative day. For this reason the prothrombin time should be determined daily for the first four days after operation and then every other day for at least eight or ten days longer. Any increase in the prothrombin time should constitute an indication for the immediate administration of a concentrate of vitamin K and bile salts by mouth or by duodenal tube. To those patients whose prothrombin clotting time before surgical treatment has

been high, it is perhaps wise to administer the vitamin and bile salts daily for several days after surgical operation, regardless of the prothrombin clotting time. A patient who has a prothrombin clotting time of more than thirty seconds should be prepared with particular care and one who has a prothrombin time of more than forty-five seconds must be considered as a potential bleeder and treated as such.

THE USE OF VITAMIN K AND THE PROTHROMBIN CLOTTING TIME IN OTHER CONDITIONS ASSOCIATED WITH AN ABNORMAL TENDENCY TO BLEED

The effectiveness of vitamin K in the treatment of the hemorrhagic diathesis of jaundice has prompted an investigation of its possible application in other hemorrhagic states. We have determined the prothrombin clotting time in a number of conditions which are associated with an abnormal tendency to bleed. These conditions are listed in table 3, together with the results of our determinations. In this series of cases the prothrombin clotting time has been normal in each instance. Concentrates of vitamin K and bile salts have been administered in the treatment of several patients having hemophilia, menorrhagia, metrorrhagia and essential hematuria, and in no instance was the normal prothrombin clotting time or coagulation time altered, nor was the tendency to bleed affected appreciably.

Dam and Glavind²⁷ in 1938 reported normal "R values" in patients having thrombopenia, aplastic anemia, hemophilia and myeloma; Dam and his associates²⁷ in 1937 were unable to lower the coagulation time of a patient suffering from hemophilia after the administration of large amounts of vitamin K. Burch and Meade²⁸ have reported a case of multiple retinal hemorrhages of unknown causation which appeared to show improvement following administration of an oil extract of hemp which possessed vitamin K activity. Similar treatment had little or no effect on the retinitis which is associated with diabetes. The observations of Burch and Meade have not as yet been confirmed.

SUMMARY

Evidence is presented which indicates that the deficiency in prothrombin associated with the hemorrhagic diathesis of obstructive jaundice can be controlled by certain fat-soluble materials present in alfalfa. Although this material, vitamin K, must for the present be considered an empiric remedy, its biologic activity in man and animals can hardly be questioned. The control of a deficiency of prothrombin depends on several factors: (1) a normal diet containing the antihemorrhagic vitamin, (2) the presence of adequate amounts of bile salts in the intestine, (3) a normal intestinal absorptive surface and (4) a physiologically normal liver.

In a majority of patients suffering from jaundice, the second and fourth factors may be impaired singly or, more usually, in combination, as the foregoing paragraphs indicate. The routine methods of treatment suggested in this report may become obsolete when vitamin K is available in pure form or when it is possible to administer this vitamin by the parenteral route. No matter which method eventually may be employed,

27. Dam, Henrik; Schönheyder, Fritz, and Lewis, Liese: The Requirement for Vitamin K of Some Different Species of Animals, *Biochem. J.* 31: 22-27 (Jan.) 1937.

the importance of anticipating the danger of prothrombin deficiency and detecting it by means of laboratory studies will remain a paramount consideration in successful treatment.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRs. SMITH, ZIFFREN, OWEN AND HOFFMAN
AND DRs. BUTT, SNELL AND OSTERBERG

DR. I. S. RAYDIN, Philadelphia: My experience with the use of materials containing vitamin K began in October 1937, when my associates and I began to use desiccated spring grasses with bile salts. Rhoads has recently reported our results. They are in general similar to those which we have just heard. Twelve years ago we reported that in the absence of a serum protein deficiency there was no deficiency in the serum calcium in obstructive jaundice. Rhoads and Warren have been studying the prothrombin content of the plasma under conditions of liver injury similar to these Dr. Smith and his co-workers have used, and the data are in agreement with theirs. In addition, they have studied the prothrombin content of the plasma of completely hepatectomized dogs and it is their opinion, as it is I am sure of the authors this morning, that the liver is probably the sole source of synthesis of prothrombin. Some of the failures to obtain satisfactory results have no doubt been due to inadequate doses of the vitamin containing substrate and to inadequate amounts of a potent bile salt preparation. Until available evidence is obtained in which substrates containing vitamin K can be accurately assayed, it is important that large doses, even overdoses of K substrates, be given, and this is true also of the bile salt preparations. Many of the bile salt preparations now available are relatively inadequate. The occasional unfavorable result which has been obtained even when large amounts of K-containing substrates and bile salts are administered is, as a rule, due to extensive liver injury. Every attempt should be made to improve the functional capacity of the liver prior to operation and to preserve its integrity after operation. I believe that, in addition to the use of substrates containing vitamin K and bile salts in this operative period, the diet of the individual should be such that the liver is conditioned against minimal injury as the result of operation and anesthesia. Such diet contains not only adequate carbohydrate but adequate protein. A liver high in fat and low in protein is maximally susceptible to injury. A liver low in fat and high in available protein is maximally resistant to such injury. It is important, therefore, that attention be paid not only to the vitamin K and bile salt requirements of these individuals but to the dietary factors which condition the degree of liver injury that may occur after the use of volatile anesthetics.

DR. JOHN D. STEWART, Boston: I have been interested recently in the phenomenon of fall in concentration of prothrombin following operation. In a group of nineteen patients operated on for obstructive jaundice an average postoperative drop in prothrombin concentration of 23 per cent was found. This is expressed in absolute percentage. The drop was maximal within three days. In these operations the various anesthetics used were procaine block and spinal and ether anesthesia, and no correlation was found between the type of agent and the extent of depression in prothrombin. On the other hand, patients without liver disease undergoing such operations as herniorrhaphy, total hysterectomy and combined abdominoperineal excision of the rectum showed an average drop of less than 5 per cent in prothrombin concentration after operation. Therefore, as yet I am inclined to regard the postoperative depression of prothrombin in obstructive jaundice as an expression of the reduction in prothrombin reserves. There is need in the clinical application of this subject for a simple, accurate method of determining the concentration of prothrombin, and also a need for a purified form of vitamin K which can be given parenterally, possibly obviating the need for giving bile salts. Dr. Smith and his co-workers have supplied us with an accurate two stage method of determining the prothrombin. This bedside method should be used widely and frequently. I was interested in the observation of Dr. Butt and his co-workers that they have encountered patients with the hemorrhagic diathesis in obstructive jaundice without reduction in the prothrombin con-

centration. It has been my lot to see ten patients with massive bleeding in obstructive jaundice, eight of them after operation, and in no case has the prothrombin level been above 40 per cent. I should like to ask Dr. Smith whether he has studied the extent of fluctuation of prothrombin in normal individuals over a period of time. I should like to ask Dr. Butt whether, in the study of various clinical conditions, he has encountered abnormal increase in the plasma prothrombin level.

E. A. DOISY, PH.D., St. Louis: Owing to the earlier work of Dam and Almquist, my associates and I have been in the fortunate position of being able to continue the biochemical work on vitamin K. Several months ago we isolated the first pure vitamin K. Shortly after that we isolated a second compound which likewise was pure and crystalline and which also possesses vitamin K properties. The first compound obtained was from putrefied fish meat. It is a solid at room temperature, a light yellow, crystalline salt. The second compound, obtained from alfalfa, is a light yellow oil at room temperature. However, it has been recrystallized a great many times at lower temperatures. Some of the important points mentioned today have been the preparation of a material which can be used parenterally. I don't believe we are now in a position to report that, but we have plans under way which I think will lead to such a preparation. Some of the speakers have been hopeful of obtaining definite indication of the amount of vitamin K to be used. That is within our grasp now that we have the crystalline material. It would be wise in the near future to do away with bile assay procedures and adopt the use of the pure compound. Moreover, if the bile assays are to be continued, it would probably be wise to adopt some permanent crystalline stable compound as a base standard, such as the League of Nations has done with a great many of the hormones and vitamins. Within the last few weeks we have attained such a compound. Vitamin preparations are notoriously unstable for alkali and light. The new compound we have seems to be a great deal more stable and perhaps is entirely stable toward light. Consequently, that will afford us a definite base standard for the assay, if assays must be continued.

J. D. GREAVES, PH.D., St. Louis: During the last ten years I have carried out experiments which indicate that bile salts are essential, at least in the rat, to the normal intestinal absorption of not only vitamin K but also vitamins D, E, B-carotene and, to a lesser extent, vitamin A. Only, however, in the case of vitamin K has a clearcut clinical deficiency been demonstrated in the clinical patient. This might seem strange, but a glance at the conditions associated with vitamin K deficiency adequately explains the discrepancy. Most fat soluble vitamins are stored in large amounts in the body and held in reserve for times of need. This is not the case with vitamin K. But small amounts of this factor have been found in the various tissues of the body. The animal or patient when placed on a deficient diet is soon depleted and deficiency symptoms show up. Furthermore, this finding is consistent with the rapid and dramatic fluctuation seen in the prothrombin levels of the patient as well as the experimental animal. The patient with biliary disease usually selects a low fat diet, low also in fat soluble vitamin factors. In the presence of complete obstruction, bile does not enter the intestine, with the result that the whole of the dietary supply is cut off. Liver injury adds an additional complication. Even after relief of the jaundiced condition the quantity and quality of the bile produced by the liver are inadequate. All these factors superimposed accentuate the deficiency, and the patient develops the hemorrhagic tendency reported by Dr. Butt. It must be remembered that potentially the body is also deprived of its supply of the other fat soluble factors when bile is removed from the intestinal tract. However, it seems that in this case the body reserves are usually adequate to meet the body's needs during the time of the deficiency. In our work on the influence of jaundice and liver poisons on the utilization of carotene and vitamin D we have found that liver damage results in faulty utilization of these factors. A similar observation has been made with vitamin K recently in bile fistula animals in which secondary complications resulted in marked liver damage. Such animals have failed to respond to even large doses of vitamin K concentrates. These observations confirm Dr. Butt's observations. Dr. Butt pointed out that we had

found the administration of vitamin K subcutaneously or orally to be effective in the relief of the deficiency symptoms of the bile fistula and jaundiced rat; however, a very large dosage of a quite highly purified material was administered; even then the parenterally administered material was not as effective as was a much smaller amount administered orally with bile salts.

DR. G. V. LEROY, Chicago: These papers on the clinical usage of vitamin K are of great interest. One is reminded of the fact that the deficiency was first discovered in an analysis of the bleeding tendency in chicks which occurred unassociated with trauma. Hematologists tend to separate the bleeding diathesis into two portions: Disturbances of the coagulation mechanism, an example of which is hemophilia. Disturbances in the mechanism which maintains the integrity of the capillary wall, an example of which is scurvy in which hemorrhage occurs independent of trauma in patients whose coagulation mechanism is apparently normal. Mixed forms are perhaps demonstrated by essential purpura. The first group has prolonged coagulation time and normal bleeding time. The latter group has the reverse. The vitamin K deficiency appears to be a mixed state. Study of this deficiency has been carried out mostly in terms of prothrombin, which is concerned with the coagulation mechanism. I would enjoy hearing any of the authors discuss the effect of vitamin K on capillary fragility, and the role, if any, of altered capillary fragility on the clinical state associated with deficiency of that vitamin.

DR. H. P. SMITH, Iowa City: Dr. Stewart asked regarding normal variations in prothrombin level. We have made determinations on normal laboratory workers and have found that the variation is rarely more than 15 per cent. In ward patients having minor illness the variation is somewhat greater. However, these patients often do show some malnutrition, and this may be important. The question of capillary fragility is perhaps of great importance in certain diseases but probably not in the jaundiced bleeder. We too have found that some patients who fail to respond to the ordinary dose of vitamin K and bile salt will respond promptly to increased dosage. One patient whose prothrombin remained low despite the usual dosage of vitamin and bile did respond promptly when the dose of bile was increased fivefold. I think we shall have to guide our therapy, as Dr. Butt suggested, by the use of prothrombin tests. I am convinced that the requirements both of vitamin K and of bile salt, vary markedly from case to case. It is encouraging to hear the results of Dr. Doisy and to know that we are going to have in the near future purified material with which to work. The various commercial products now available vary tremendously, and their potency is largely unknown.

DR. HUGH R. BUTT, Rochester, Minn.: In answer to the question by Dr. Stewart concerning the abnormal increase in the level of prothrombin following administration of concentrates of vitamin K, we have given as much as 20 Gm. of the crude concentrate of alfalfa together with bile salts by mouth over a period of two or three days or as much as 13 Gm. of the crude concentrate of alfalfa mixed with peanut oil by the intramuscular route without any untoward reactions and without any abnormal increase above the normal level of the prothrombin in the blood. Concerning the effect of concentrates containing vitamin K on ordinary laboratory coagulation and bleeding times, in the past the experience among surgeons indicated that coagulation and bleeding times as determined by standard methods are altered little until the patient is on the very brink of bleeding or is actively bleeding. Finally, laboratory tests, such as those developed by Dr. Quick and his associates and by Dr. Smith and his associates, enable us to detect early an apparent nutritional deficiency and make early treatment possible. As Dr. Elvehjem has said in another connection, the time to treat deficiency states is when they are detected by laboratory procedures rather than awaiting the appearance of definite clinical symptoms. I should like to stress the importance of not relying too strongly on any single determination of the level of prothrombin. A blood may appear to be normally coagulable but within a few hours it may become virtually incoagulable. Those who have followed many of these patients have had the opportunity to see the terrible misfortune that can happen by depending too much on any laboratory procedure.

A question which I think is most important has already been stressed by Dr. Ravdin. The normal level of prothrombin is little affected following operation in patients with normal liver function or with minimal injury to the liver. However, patients who have slightly more than the minimal liver damage or, as usually is the case, have much liver damage, are markedly affected by anesthetics and by surgical procedures, and these patients bear the most careful attention in preventing cholemic bleeding during the postoperative period.

RABIES IN BIRMINGHAM, ALABAMA

HUMAN MORTALITY AS AFFECTED BY ANTIRABIES TREATMENTS

GEORGE A. DENISON, M.D.

Director of Laboratories, Jefferson County Health Department
AND

J. D. DOWLING, M.D.

Health Officer, Jefferson County, Ala.
BIRMINGHAM, ALA.

In this paper we deal with the experiences of a local health department in the prevention of rabies among human beings. We are especially concerned with those problems which confront the physician; namely, the value of antirabies vaccine and indication for its administration.

The difficulties involved in maintaining continuous programs for the enforced confinement of dogs, along with the failure to find other effective control measures, has greatly intensified the problem of rabies. Through failure to control the dog, increased reliance has been placed in secondary control measures. Antirabies vaccine has been administered to an ever increasing number of persons who become exposed to an ever increasing number of rabid dogs.

* By 1938 census.

The original Pasteur treatment and its several modifications have become generally accepted as reasonably safe and highly effective in preventing rabies among human beings. This, together with the ready availability of the vaccine, the ease of its administration, the morbid fears of a misinformed public regarding the disease, the apparent 100 per cent mortality among those actually infected and untreated and the general failure on the part of responsible parties to limit treatment to those for whom it is definitely indicated, are all factors which commonly lead to the indiscriminate administration of vaccine.

In epidemic areas the attitude of the public is a real handicap to the medical adviser, for there is probably no disease about which the public is more misinformed. The fears, horrors and superstitions of the exposed individual, magnified by a superabundance of bad advice obtained from well meaning friends, often produce a state of panic before a physician is reached. Circumstances of exposure so infinitely remote as to make the

possibilities of infection ridiculous and unworthy of even momentary consideration often cause such extreme mental anguish that nothing short of vaccine treatment can prevent nervous collapse of the individual. "Undue apprehension" is probably as common a symptom among the many recently exposed persons as it is among the very few who develop the disease clinically. Under such circumstances the individual is often unable or unwilling to accept medical advice and insists on vaccine treatment, while the physician too often fails to maintain a professional attitude and allows himself to be influenced by the undue apprehension of the patient.

INCIDENCE OF RABID ANIMALS IN BIRMINGHAM AND IN ALABAMA

The incidence of rabies in Alabama has been variously reported.¹ During the seventeen year period 1922 to 1939 a total of 11,218 animals have received a positive laboratory diagnosis of rabies, 42,947 individuals were given antirabies vaccine and forty-eight persons died of the disease.

Birmingham has been considered by some as the "rabies capital" of North America and possibly of the civilized world. Further, the incidence of the disease in the surrounding county of Jefferson is not materially less than in the corporate limits of the city.

Birmingham, located in north central Alabama, covers an area of 54 square miles. It is essentially industrial and largely devoted to the manufacture of iron products and building materials. The health department has divided the city into fifty-two census tracts, which average a square mile in area and about 5,000 in population. Census figures for both human and dog populations were determined in 1938 by actual survey made as a WPA project under supervision of the health department (table 1). The total population of 256,203 is 40 per cent Negro. The dog census enumerated 20,609 dogs for which ownership was established. The actual number is much higher, as it was obviously impossible to count ownerless strays.

During the last ten years (1929 to 1939) in Birmingham (table 2) a total of 1,495 animals have received a positive laboratory diagnosis of rabies, 5,206 persons received antirabies vaccine and three persons died of the disease. Since 1931 the number of known rabid animals has not dropped below 100 annually except in 1935, when effective control measures were temporarily enforced. In Jefferson County, which includes Birmingham, the incidence from year to year has varied markedly though the general trend is definitely upward; 1938 constituted the year of maximum incidence with a total of 443 known rabid animals. In Birmingham alone in 1938 slightly more than 1 per cent of the owned dog population was known to have developed rabies. This increase is actual and is based on the larger number of animals examined each year as well as a steady increase in the percentage of positive observations. The indicated rise in rabies here is quite evidently a true one and represents a deepening of the animal reservoir of this infection.

As incredible as these figures may appear, they do not express the true prevalence. They represent largely the incidence of rabies among pets of those persons intelligent enough to suspect the disease and interested enough to bring the animal heads to the laboratory. Failure of dog owners to recognize clinical symptoms,

which frequently are atypical, and the tendency of rabid animals to leave their home environment result in failure even to suspect many animals. Negroes are too unconcerned and too uninformed to suspect rabies. During 1938 in Birmingham only thirty-one, or 12.5 per cent, of 245 rabid animals were submitted to us by Negroes despite the fact that Negroes constitute 40 per cent of the population and are known to have almost as many dogs per family as white persons (table 1).

Further illustration is afforded by a study of the various census tracts as shown in table 3. If the data from these tracts are assembled on the basis of dog ownership, it is found that in those areas where Negroes own from 75 to 100 per cent of all dogs the reported incidence of rabies is lowest (0.5 per cent) but becomes progressively higher (to 1.5 per cent) as the percentage of white owned dogs increases. This, of course, represents incompleteness of data, not true incidence.

The almost total disregard of rabies by Negroes is again shown by studies undertaken to determine the effectiveness of prophylactic canine vaccination. Negroes in Birmingham vaccinated 10 per cent (799) of their dogs during 1938 and of these not one was found rabid. On the other hand, white persons vac-

TABLE 2.—Prevalence of Rabies in Birmingham, Ala.

* Including nineteen micronegative, mouse positive examinations.

inated 40 per cent (5,107) of their dogs and of these 0.5 per cent (twenty-six) were submitted for examination and found rabid. Obviously the effectiveness of canine vaccination does not depend on the color of the dog owner, and such a difference in the reporting of vaccine failures represents neglect on the part of the Negro to seek a diagnosis of animals either killed or dying of disease.

RELATION BETWEEN HUMAN MORTALITY FROM RABIES AND THE ADMINISTRATION OF ANTIRABIES VACCINE

The data presented are sufficient to indicate that the prevalence of rabies among dogs in Alabama generally, and in Birmingham in particular, is sufficiently great to constitute a potential danger of high degree to the human population. One might expect human deaths from rabies to be frequent but, as a matter of fact, they are quite unusual. The exact reason for this is not clear, but the following facts show that it is by no means entirely due to the wholesale and indiscriminate administration of vaccine.

During the past seventeen years 42,947 persons received antirabies vaccine in Alabama with a mortality from rabies of only 0.06 per cent. This low rate, according to the usual interpretation of treatment statistics, constitutes a very favorable showing for effective

1. Denison, George A.: Rabies: Prevalence, Treatment, Control, J. M. A. Alabama, March 1935. Baker, J. N.; McAlpine, J. G., and Dowling, J. D.: Rabies: A Continuing Challenge, South. M. J. 29: 547-557 (June) 1936. Denison, McAlpine and Gill.²

treatment. But perhaps of greater significance is the fact that of the forty-eight persons who died of rabies during the same period, twenty-three, or 48 per cent, were judged to have received prompt² and adequate treatment.³ The persistence with which fatalities continue to be equally distributed among the treated and untreated affords ground for wide speculation.

The Alabama State Health Department distributes Semple vaccine without charge to physicians for the treatment of those exposed to rabid animals. The department also pays a nominal fee to the physician for the administration of vaccine to each indigent person. Since July 1933 detailed questionnaire forms have accompanied each treatment, and to January 1939 some 10,000 of these forms, representing 44 per cent of all treatments issued for the same period, have been returned and studied. A summary of the facts contained therein is given in table 4.

These data show that the dog is the principal animal involved, and experience indicates that the dog is directly responsible for the spread of the disease to those other animals which were responsible for the remaining treatments. A high percentage (62.1) of animals to which treated individuals were exposed received either a clinical or a laboratory diagnosis of rabies. The extremely high percentage of exposures of the upper extremities greatly exceeds that reported by McKendrick⁴ and is the result not only of bites but of indirect exposure through handling animals with or without cuts or abrasions on the hands. Actually 43.3 per cent of all persons on whom information is available took treatment without having been bitten. Negroes seldom take treatment unless bitten and in fact took only 10 per cent of all treatments administered; yet they suffered only fourteen fatalities as compared to thirty-four fatalities in the white population.

The population of Alabama, according to the 1930 census, is 64 per cent white and 36 per cent Negro. The rate at which white persons take vaccine treatment is five times that for Negroes for all types of exposure and four times that for Negroes when only actual bites are considered. Expressed in another way, these data would indicate that, if the 3,000,000 people in Alabama

to judge their meaning. For example, in Birmingham we know that (1) Negroes have practically as many dogs per family as white persons (table 1). Their animals are subject to the poorest of care, and Negroes undoubtedly are bitten and otherwise exposed to rabies as often as the white persons; (2) Negroes submit only one seventh as many rabid animals to the laboratory as do white persons; (3) the rate at which Negroes take treatment is only one sixth that of the white population, and (4) during the ten year period of study

* Analysis of questionnaires from July 1933 to January 1939; types of exposure among those receiving vaccine.

Negroes suffered only two deaths from rabies and white persons only one. It is remarkable that, in an area where the risk of exposure appears so great, the Negro population can so completely ignore rabies without disaster.

In the experiences cited there is little relation between mortality from rabies and the administration of antirabies vaccine, for (1) among the highly exposed untreated (Negro) population fatalities are no greater than among the highly exposed treated (white) population, and (2) such rare fatalities as do occur are equally distributed among the treated and the untreated. An explanation of these data should probably assume a high degree of resistance to natural infection in the vast majority of both races and an occasional failure of either natural resistance or vaccine treatment to protect when infection is massive or well placed or when for some unknown reason individuals may be peculiarly susceptible. It is not inferred from this that vaccine is without value but rather that its value has been greatly exaggerated. This exaggeration is largely the result of the inclusion in treatment records of large numbers of individuals who, although definitely exposed to risk, would not have developed the disease, and also by the inclusion of many others whose exposure to risk was too insignificant even to warrant vaccine treatment.

ADVISABILITY OF TREATMENT (BIRMINGHAM PROCEDURE)

Recognition of these factors in Birmingham has led to the adoption of a more rigid procedure regarding treatment. A concerted effort is made to limit the administration of vaccine to those most probably infected by direct exposure.

The frequent attitude of the public toward treatment was expressed at the beginning of this discussion. The attitude of perhaps the majority of physicians was quite well expressed in a recent article⁵ which stated that

5. Blatt, Maurice L.; Hoffman, Samuel J., and Schneider, Maurice: Rabies: Report of Twelve Cases with a Discussion of Prophylaxis, J. A. M. A. 111: 688-691 (Aug. 20) 1938.

TABLE 3.—*Dog Ownership in Relation to Apparent Incidence of Rabies at Birmingham, Ala., for 1938*

were all white, and the same ratio of treatments prevailed, one could expect an increase of 40 per cent in the number of treatments issued per annum with no significant change in mortality. Likewise, if the 3,000,000 people in Alabama were all Negroes we would expect a 72 per cent decrease in treatments with no significant change in mortality.

Data for racial distribution of treatments and fatalities from rabies are practically the same for Alabama, Birmingham and Jefferson County. In Birmingham we have more complete collateral information on which

2. Starting within seven days following exposure. Twenty-four were treated, but for one treatment was delayed three weeks.

3. Denison, George A.; McAlpine, J. G., and Gill, D. G.: Rabies Deaths in Alabama, Am. J. Pub. Health 27: 869-874 (Sept.) 1937.

4. McKendrick, A. G.: Seventh Analytical Review of Reports from Pasteur Institutes on the Results of Antirabies Treatment, Quart. Bull. Health Organ., League of Nations, Geneva 6: 1 (Feb.) 1937.

"antirabies vaccine should be administered to any person bitten by, or contaminated in any way by the saliva of an animal known to be rabid." Both attitudes are expressions of failure to evaluate the risk of exposure or the risk of treatment complications and reflect an unwillingness to assume responsibility.

In Birmingham all vaccine is distributed by the bureau of laboratories of the health department, and in every case careful scrutiny is made of the exposure history. Individuals making direct application are advised and if treatment is necessary are referred to their physician of choice. However, the majority of individuals seen at the health department are those sent in by physicians for advice. Such advice regarding treatment is communicated to the physician, who makes final disposition of the case. Vaccine is released only on the verbal or written order of the physician, and usually only after the merits of the individual case have been freely discussed between the physician and the laboratory director.

Disposition of the Animal.—Whether the animal appears normal or sick, it should be quarantined for a period of from ten to fourteen days. If typical symptoms of rabies develop, the treatment need not be further delayed. Confirmation of diagnosis, however, should be made at autopsy. If death occurs within the period of observation, early microscopic examination of the brain is made. If positive, treatment is begun. If negative, the clinical symptoms of the animal must be taken into consideration in an effort to arrive at a diagnosis. The importance of clinical observation is apparent when the limitations of direct microscopic examination for Negri bodies is appreciated. Leach⁶ has determined the presence of rabies virus in brain material by both mouse inoculation and direct microscopic examination. He reports positive mouse tests for 12 per cent of brains on which Negri bodies were not found by direct microscopic examination, and negative mouse tests among 0.9 per cent of brains on which Negri bodies were reported as found by experienced technicians.

In endemic areas such as Birmingham every dog that bites should be considered rabid until known to be otherwise. When the condition of the animal is unknown because it cannot be located or cannot be positively identified or the laboratory examination is unsatisfactory, it is advisable to administer treatment to those bitten.

These procedures are quite generally followed in Alabama with apparent safety. In Birmingham treatment ordinarily is delayed until the animal has died and the diagnosis has been established. Face bites and multiple bites are, of course, excepted.

Actual Bites or Scratches.—For actual bites or scratches made by the teeth or claws, treatment is always advisable. In the case of bites above the shoulders or multiple severe lacerations of the body or extremities, treatment should be started immediately but may be discontinued later if the animal proves not to be rabid. In some instances it is probably safe to wait from twenty-four to forty-eight hours if the history of the dog is known and if it can be observed by an experienced veterinarian; but, unless the animal remains perfectly normal, treatment should not be further delayed. For other bites it is safe and usually desirable

to delay treatment until a definite diagnosis can be made either clinically or by laboratory procedure.

Complete reliance in the effectiveness of antirabies vaccine is never justified, and cauterization of wounds made by the animal with strong nitric acid is necessary for adequate protection of the patient. There is no substitute for nitric acid; mercurochrome and agents which coagulate the tissues are worthless. If areas of heavy nerve distribution are involved, the use of nitric acid is all the more imperative. In ten years' experience we have seen only one wound that had received proper local treatment.

Other Exposures Requiring Treatment.—The point to emphasize is that treatment is usually advisable only following an actual bite or scratch made by the suspected animal. Other extenuating circumstances, of no great importance, sometimes warrant treatment as, for example, the known contamination of fresh open wounds with saliva. Such an exposure assumes the importance of a bite only if there is some abrading force to carry the saliva into the wound. The wound itself is of importance only if it was of sufficient size to have been easily noticed, and provided it had been made on the day of the exposure to the animal. It is not felt that the mere handling of rabid animals with fresh open cuts on exposed parts is important unless there is direct contamination with saliva and, unless such contact is known to have occurred, treatment is not advised.

When infants and young children have had intimate contact with rabid animals for extended periods of time, treatment may be advisable, especially if the parents are unobservant or ignorant of what may have transpired. Fifty per cent of deaths from rabies in Alabama occur in children under 13 years of age.

Treatment has occasionally been advised for highly nervous women, not for the prevention of rabies but to avoid nervous collapse or hysteria. Two such individuals were treated because of definite rabies psychosis.

When Treatment Is Not Advised.—Treatment is not advised following (1) contamination of old cuts, sores, abrasions, scratches or hangnails with saliva of known rabid animals; (2) "pinches" in which the skin is definitely broken but the clothing neither torn nor penetrated; (3) handling, eating after, sleeping with, kissing or other intimate exposure to rabid animals; (4) drinking milk of rabid cows, eating meat of rabid animals; (5) bites of any animal living fourteen days from the time of biting; (6) bites from fleas from rabid animals; (7) any exposure to a case of human rabies other than an actual bite, or direct contamination of fresh open wounds, or (8) any exposure of a nonrabid animal just bitten by a rabid animal except when infected saliva is directly transmitted to a fresh open wound.

While, theoretically, rabies can be contracted from these and many other types of exposure, it practically never occurs. Vaccine paralysis, or other serious complications resulting from administration of vaccine, are probably more frequent than the development of rabies from any exposure other than an actual bite; and, in advising treatment one should carefully weigh the possibilities of death or permanent injury from vaccine against the possibilities of death from rabies.

Four known paralytic accidents have occurred in Alabama with the administration of 33,147 Semple treatments, an incidence of one in 8,287. Of the forty-

6. Leach, Charles N.: Comparative Methods of Diagnosis of Rabies in Animals. Am. J. Pub. Health 28: 162-166 (Feb.) 1938.

five⁷ deaths in Alabama on which there is definite history regarding the type of exposure, all the victims are known to have been bitten. These two facts contain the whole wisdom of withholding treatments from those not actually exposed.

The following histories of exposure, for which treatment was administered in Alabama, were taken from questionnaire forms. They are selected to illustrate conditions for which treatment would not have been advised in Birmingham:

1. No known exposure, treatment given as a safeguard.
2. Bathed in water which was used in washing a child that had been bitten by a rabid dog.
3. Treated wounds of child, no contact with rabid animal.
4. Saliva from rabid animal got in hair.
5. Handled clothing of grandson who played with rabid dog.
6. Patient had wound on finger when washing out tub from which rabid cow drank water.
7. Dressed chicken which had been killed by rabid dog.
8. Had small abrasions of hands and handled chain with which rabid animal was tied.
9. Drank milk from rabid cow.
10. Milked cow that was rabid.

The following histories of contact with known rabid animals are characteristic of many for which treatment

Average number of treatments per known rabid animal.

was not advised and not administered in Birmingham. These summaries are taken from records of exposure for May and June 1938:

1. A bottle used to give medicine to a rabid dog was discarded and was immediately picked up by a baby, who placed the mouth and neck of the bottle in its mouth.
2. Handling and petting rabid dog, also kissing.
3. Individual claiming to have a gastric ulcer drank milk of a rabid cow.
4. Had hands in mouth of rabid dog; briar scratch and barbed-wire cut on hands made the day before.
5. Handled and drenched rabid calf throughout its illness. No cuts or scratches on hands.
6. Handled dog about mouth and head. Had scratches on hand which were not made by the animal.
7. Mechanic had small fresh cuts and abrasions on hands. Handled rabid dog about head while transporting animal in automobile.
8. Had hands in mouth of rabid dog trying to remove "bone from throat." No visible cuts or abrasions at the time.
9. Six members of a family handled rabid dog throughout illness. None were bitten or scratched by animal, all had minor abrasions on hands.

7. Of the remaining three deaths in the state no information regarding exposure is available and nothing is known except that one victim was a child of 3 years, one a man of 63, a stranger in the community about whom little was known; one was a man of 80 who developed rabies two days after "doctoring" a rabid dog, but he unquestionably received his infection at least several weeks earlier.

10. Handled rope with which rabid dog was tied, handled dog's head after its removal from carcass. Had superficial fresh abrasions on hands.

If the indications for and against the administration of treatment, as given in this discussion, appear to depart considerably from all accepted procedures, it should be remembered that they have been followed in Birmingham for the past ten years in advising approximately 10,000 individuals, as yet without a fatality.

It is not intended to imply that all lay persons and physicians in Jefferson County follow this advice. On the contrary, only about one third to one half of them do. Nevertheless it is felt that some reduction in the useless administration of vaccine has been accomplished. The accompanying chart correlates by year the average number of Semple treatments given for each known rabid animal for Alabama (exclusive of Jefferson County) with the same information for Jefferson County. Treatments for the latter are considerably lower and show a more definite downward trend than in the remainder of the state. This has been accomplished without an increase in mortality.

A word of warning should be directed to those who may wish to follow the procedures outlined in advising treatment. The problems of the exposed individual should never be viewed with contempt. No matter how remote the contact with an infected animal may appear, a careful history is essential to eliminate the possibility of real exposure. Only after careful consideration is a decision justified.

SUMMARY

The incidence of rabies among animals in Birmingham, Ala., has steadily risen during the past ten years. The increase is actual and is based on the larger number of animals examined each year, as well as a steady increase in the percentage of positive observations. The problem appears to be largely one of unconfined, home owned dogs (pets); very few unidentified animals are received for examination. The year's total of rabid dogs approximates 1 per cent of the known dog population. This figure is largely made up of dogs submitted for examination by white owners and would probably be doubled if Negroes were equally cautious.

During a period of ten years, 5,206 vaccine treatments were administered to human beings. While Negroes constitute 40 per cent of the population, they submitted only 12.5 per cent of all rabid animals, took only 10 per cent of all treatments and, like the white population, suffered only a rare mortality. Figures for the state as a whole substantiate these data. There appears to be little relation between mortality from rabies and the administration of vaccine.

The Birmingham procedure recommends treatment only for those quite definitely exposed to rabid animals.

CONCLUSIONS

The data presented are not of a type to warrant definite conclusions. The following general statements are offered as implicit in the experience cited:

1. Rabies is primarily a veterinary problem. Regardless of its prevalence among dogs, it will probably never cause sufficient morbidity or mortality among human beings in this region to allow its classification as a public health problem of importance.

2. If rabies were as easily contracted by man as is commonly supposed, it would in Alabama become one of the leading causes of death. Instead, it continues to be a very rare disease.

3. In this region there appears to be little relation between mortality from rabies and the administration of antirabies vaccine.

4. Aside from an actual bite or scratch, circumstances of exposure rarely warrant vaccine treatment.

5. When considering the advisability of treatment for exposures other than an actual bite, the possibilities of vaccine paralysis or other serious complications should be considered.

6. The problem of rabies, as it is known in Birmingham, appears to be one of home owned dogs (pets) and not of unidentified strays.

SPERM EXAMINATION ACCORDING TO THE PRESENT STATE OF RESEARCH

OTAKAR JAROSLAV POLLÁK, M.D., D.Sc.

BRNO, CZECHOSLOVAKIA
AND

CHARLES AKIBA JOËL, M.D.

JERUSALEM, PALESTINE

The examination of semen as it is generally done is quite inadequate. Usually the contents of the condom are examined for (1) semen fibers and (2) mobile semen fibers and the number of mobile semen fibers is roughly computed.

Owing to the recent research by Macomber and Sanders, Mönch, Stiasny and Generales, Michael, and Joël and Pollák, the exact obstructions to fecundity in a man can be ascertained.

Fig. 1.—A stained smear; oligospermia with an increase of abnormal sperms (16 per cent) and cells (20 per cent).

There are three conditions to be observed in investigation of the sperm:

1. The examination should be preceded by a pause in ejaculation of from four to seven days at least. Only one ejaculation should take place in order to provide material for examination.

2. The material should if possible be obtained by the physician through auto-erotic manipulation or coitus interruptus. The contents of the condom are unsuitable, and other ways of obtaining material are inadequate.

3. The material should be examined within thirty to sixty minutes. Graduated vials are suitable for eventual transport. The material is to be protected against high temperatures.

History taking and clinical examination should always precede sperm examination. Attention should be paid to (1) family history, including the physical

Fig. 2.—Histologic section; normal spermia with 0.5 per cent of cells.

and mental condition and the profession of the parents, grandparents, brothers and sisters of both the husband and the wife; (2) the personal history, including former diseases such as parotitis, tuberculosis, syphilis, gonorrhea, rheumatism and mental diseases, as well as accidents, and (3) the sexual history, including all particulars of the sexual life of the husband and wife before, in and outside their marriage, obtained first in separate interviews and then in a mutual interview, the duration of their marriage and the number and nature of the cohabitations being investigated.

The clinical examination concerns the type of constitution, the mental and physical health and, especially, the primary and secondary sex characteristics.

After having obtained all these facts, part of which are included in the examination report, we proceed to the macroscopic examination of the ejaculate. This concerns:

1. The quantity, which normally amounts to from 3 to 5 cc. (average, 3.3 cc.) under the conditions mentioned. Smaller quantities (about 0.5 cc.) usually are pathologic, whereas larger ones are not.

2. The consistency of the fresh ejaculate. This is of a specially gelatinous character but when exposed to fresh air changes in from ten to thirty minutes. The partly liquefied, somewhat slimy fibrous ejaculate containing white flakes is then examined. An originally thin ejaculate is usually poor in semen fibers, whereas a thick ejaculate, which does not liquefy readily, often is pathologic.

3. Color and smell. These will be noticed only in pathologic specimens.

Because definite conclusions cannot be drawn from the macroscopic investigation alone, the microscopic investigation is actually more important.

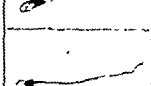

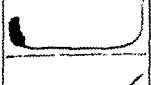

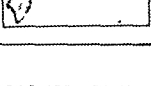

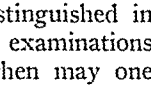

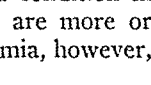

After the ejaculate is liquefied we make a preliminary preparation. The ejaculate is well mixed with a fine

glass capillary tube and a drop put on an object-bearer. This may be covered or, when a concave object-bearer is used, regarded as a hanging drop. If no sperms are found after repeated examination, the ejaculate should be thoroughly centrifuged. In case of extreme oligospermia it is necessary to concentrate the material. If this method does not produce the desired result, it is

$\times 400,000/256 = m$ (n is the number of sperms to sixteen large squares and m is the number of sperms per cubic centimeter). Normally the number of sperms in 1 cc. varies between 60 and 120 millions. Higher numbers (hyperspermia) are generally not pathologic, and lower numbers (hypospermia or oligospermia) are detrimental to the prognosis.

The number of motile sperms is determined by means of the Ehrlich ocular screen, which divides the field of vision into four quadrants. Given the aforementioned conditions, especially when examination takes place within thirty to sixty minutes after the material is obtained, normally at least 80 per cent of all semen fibers are motile. We use the terms normokinesis, hyperkinesis and hypokinesis to express the degree of motility, whereas we express the number of motile sperms in percentages of the aggregate of semen fibers. A decline of the motile sperms usually accompanies a decline of the degree of motility. This condition is called asthenospermia.

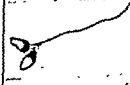

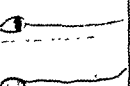

TABLE 1.—Spermiogram According to Pollák and Joël, I-IV

(c) Depigmented	

necessary to examine colored smears, because sometimes slime-covered sperm cannot be distinguished in the original preparation. When all these examinations have a negative result, then and only then may one speak of azoospermia. Azoospermia is a condition in which one cannot find sperms but there are more or less ripe cells of spermiogenesis. In aspermia, however, one can find neither sperms nor cells.

To determine the number of sperms the ejaculate is mixed thoroughly by means of a capillary tube and drawn up to the 0.05 mark of an erythrocyte-mixing pipet. A diluting fluid is then drawn up to the 1.01 mark, the most suitable fluid being physiologic solution of sodium chloride to which has been added carbol-fuchsin 0.1 cc. to 100 cc. The mixture is well shaken and a Thoma-Zeiss counting chamber filled. The counting is repeated twice in order to obtain results as accurate as possible. Sixteen large squares (i. e. $16 \times 16 = 256$ small squares) are to be counted. In the calculation we divide by 256 to obtain the number to a small square, multiply according to the dilution by 200 and according to the chamber measures by 400,000 (one small square amounts to 0.0025 cu. mm. and the chamber depth to 0.1 mm.). The formula is now: $n \times 200$

When no motile sperms are found, we try to call forth motility. As actual necrospermia is very rare, stimulating efforts are often successful. In most cases in which no motile semen fibers are found, one is dealing with suspended animation, a latent akinesis, an immobilization. Our stimulating efforts with isotonic solutions of magnesium salts change the image essentially. We make the solution by mixing 8 parts of a 5.42 per cent dextrose solution with 2 parts of an eighth normal solution of magnesium hydroxide, magnesium chloride or magnesium sulfate. A glass capil-

lary tube 12 or 15 cm. long and 1 mm. in broad diameter is marked lengthwise at 1 cm. and at 10 cm. The thoroughly mixed ejaculate is drawn up to the first mark and the diluting solution to the second mark. The contents are mixed by drawing up and blowing out the contents twice. Then we transfer the solution to the cavity of a concave object-bearer. The cavity is filled

entirely, air bubbles should be avoided and the whole is covered with a covering glass. The preparation is observed under the microscope for ten minutes. If we do not perceive any movement within this time, we speak of necrospermia. In case of failure the experiment is repeated. We make use of the same experiment in cases in which there are a large number of akinetic sperms or in cases of high grade hypokinesis. Under the influence of the magnesium solutions we often improve the original results.

In a special laboratory we can perform resistance experiments, using hypertonic and isotonic solutions. For hypertonic solutions we use 15 per cent hydrochloric acid, 0.5 per cent acetic acid and 70 per cent alcohol, and for isotonic solutions we use eighth normal sodium hydroxide and eighth normal sodium carbonate in dextrose solution. The procedure is the same as that of the stimulating efforts. The capacity for resistance, which should be present in acids as well as in alkalis, can of course be measured only in normal or approximately normal motile sperms.

The examination of original preparations is followed by the examination of colored smears. An experienced observer may be able to discern differences in the shape

and size of the sperms in the original preparation, but these stand out clearer in supravital coloring. By the addition of one drop of 1 per cent watery solution of brilliant cresyl blue the motility of the sperms is influenced so slightly as to leave sufficient time for observation. One can judge the number of motile abnormally shaped sperms and the number of immotile normal sperms. Thus one is enabled to distinguish between natural and artificial products. This makes the observation of colored smears a great deal easier.

Colored smears are the most suitable for the differentiation of structures of sperms and of cells of spermiogenesis. The smears, which are prepared like blood smears, must be as thin as possible. They are dried in fresh air by fanning and are fixed and colored. One part of the preparation is colored with hemalaun¹-eosin and the other with azur-eosin. The two stains complement each other, because the structure of the sperms is better visible with the first and the structure of the cells more easily distinguished with the second.

TABLE 4.—Spermiogram: VII. Other Cells; VIII. Elements

VII. Other cells:	
(a) Macrophage

(c) Fat crystals	
(d) Böttcher crystals	
(e) Testicle cylinders	

For coloring with hemalaun-eosin the preparation is fixed for two minutes with methyl alcohol, refluxed for five minutes with 95 per cent and 70 per cent ethyl alcohol and then rinsed quickly in water. It is then

1. Hemalaun is similar to hematoxylin but not identical. It is a 2 per cent solution of crystalline hematin in 95 per cent alcohol 5 cc. and a 5 per cent aqueous solution of $KAl(SO_4)_2 \cdot 12H_2O$ 100 cc.

colored for twenty minutes with hemalaun, steeped in running water for thirty minutes or, if possible, twelve hours, colored a second time for five minutes with fresh hemalaun, rinsed for ten minutes in water, colored for contrast for three minutes with a 3 per cent alcoholic eosin solution, differentiated in an alcohol sequence of 70, 90 and 100 per cent, cleared in carbolyxylene and embedded in Canada balsam under a covering glass.

For coloring with azur-eosin, the preparation is fixed for two minutes with methyl alcohol, colored for twenty minutes with a diluted Giemsa-Romanowski azur-eosin solution, rinsed in distilled water and embedded in Canada balsam under a covering glass. The coloring solution is prepared fresh each time; to 5 cc. of distilled water is added ten drops of the Giemsa-Romanowski solution.

The preparations are then examined by means of immersion, and at least 200 sperms and cells are counted. Normal ejaculates have 80 per cent of morphologically normal sperms and thus at the most 20 per cent of abnormal ones. The normal relation is from 0.25 to 2 cells of spermiogenesis to 100 ripe sperms. In cases of pathologic change, the number of abnormal sperms, the number of cells of spermiogenesis or both may be increased. The maximal pathologic numbers we have found are 86 per cent of abnormal sperms and 60 per cent of cells in the same case. With azoospermia one finds only cells. Besides sperms and cells of spermiogenesis, other cellular substances and elements are to be found. The other cells include macrophages, microphages, spermiophages, real and unreal giant cells, Sertoli cells, epithelium cells of the seminal and urinary tract, and leukocytes. The elements include

Fig. 3.—Histologic section; asthenospermia with 60 per cent of cells.

prostate and lecithin corpuscles, fat crystals, Böttcher crystals and testicle cylinders.

Using the works of Mönch and the spermiogram of Stiasny and Generales as a basis, we set up a new formula for practical use. The results of our experiments and experience have driven us to changes and far-reaching alterations in the spermiogram.

The histologic investigation finally completes the examination of the ejaculate. This enables one to

study exactly the morphologic picture, the cell structures, to locate the trouble and to judge the nature of the trouble in the progress of the spermiogenesis. Our method offers special advantages in judging the therapeutic results, which show earlier with cells of spermiogenesis than with ripe spermatozooids. The embedding and coloring of sections is the work of a specialist and

Fig. 4.—Histologic section: Sertoli cells (0.25 per cent); cells 20 per cent. These sections were exhibited at the fifth Congress of Cytologists at Zurich in August 1938.

therefore it is advisable to pour a 4 per cent solution of formaldehyde on the rest of the examined ejaculate and to submit this for the purpose of histologic research to the special laboratory.

With this method of examination it is possible to distinguish between azoospermia and aspermia, to limit the expressions necrospermia and asthenospermia, and to establish various diseases such as localized degenerative-regenerative processes in the testicle, testicular atrophy, testicular hypoplasia, abnormalities of the epididymis, especially after gonorrhea, and, finally, derangements in the distal part of the seminal-urinary tract. Thus it is possible to form a reliable opinion about the fecundity of a man.

Free Institutions and Scientific Progress.—Relative to the first decade of the century, progress has been striking, but due consideration of the many aspects of the subject convinces one that continued advance in science and industry cannot be maintained unless scientific methods and an enduring probity are practiced in the conduct of government, in the drafting and application of laws, and in the conduct of public business generally. . . . The presence of a relatively large number of enthusiastic and talented young scientific men in our universities is certainly one of the necessary factors for good progress, but this alone would have been insufficient to account for the American miracle. The factor of tremendous importance, perhaps even decisive, was indubitably the existence of our free institutions, financially independent and unhampered by centralized bureaucratic control. Their liberating influence over successive generations produced a type well suited to widening intellectual frontiers. Self reliance and resourcefulness probably came to be inherent characteristics in a people who have the stamina needed to settle a continent in a relatively short time. —Keyes, F. G.: *Science* 89:209 (March 10) 1939.

REFLEX BILIARY DYSKINESIA
RELIEVED BY APPEN-
DECTOMY

REPORT OF THREE CASES

R. FRANKLIN CARTER, M.D.

AND

RICHARD HOTZ, M.D.

NEW YORK

There is a mass of clinical evidence establishing the relationship between true cholecystitis and appendicitis. The research of Rosenow¹ and the clinical observations of Heyd,² Deaver,³ Mayo,⁴ Latham and English⁵ and Draper⁶ are examples of the attention this relationship has received in the literature. Rivers and Hartman⁷ found that 31.8 per cent of 879 patients operated on for true cholecystic disease had chronic or acute appendicitis, and Draper,⁶ more recently, found that 40.6 per cent of his patients with operative cholecystitis and cholelithiasis had concomitant appendicitis.

In view of the clinical relationship between cholecystitis and appendicitis, it has been supposed that a diseased appendix may be the cause of a reflex disturbance in the biliary tract. Dyskinesia of the gallbladder and the sphincter of Oddi is now a well established clinical entity. Oddi,⁸ Aschoff and Bacmeister⁹ and Berg¹⁰ were leaders in opening the field of the neurogenic origin of disturbances of the biliary tract. Westphal¹¹ gave perhaps the greatest impetus to the conception of functional and reflex disturbances of the biliary tract. His work has been both substantiated and elaborated on by Ivy,¹² Whitaker,¹³ Ivy and Sandblom,¹⁴ Greene, Twiss and Carter,¹⁵ Best and Hicken¹⁶ and Hill,¹⁷ as well as many others.

The diagnosis of dyskinesia of the gallbladder rests on three definite observations, namely an irregular symptom complex of pain in the right upper quadrant

or colic, nausea, distention, diffuse tenderness and vomiting; a cholecystogram showing a normally concentrating gallbladder with delayed evacuation, and biliary drainage showing a failure of the gallbladder to respond normally to stimulation with magnesium sulfate and olive oil.

A search of the recent American literature fails to reveal the report of an authenticated case in which dyskinesia of the gallbladder has been relieved by appendectomy.

References and case reports have appeared in the foreign literature claiming relief from biliary dyskinesia through the removal of a diseased appendix. Norsa¹⁸ gave evidence of complete relief from pyloroduodenal spasm following appendectomy, with x-ray evidence of a return of normal pyloric and duodenal function.

Fig. 1 (case 1).—A and B, preoperative cholecystograms, A taken fifteen hours after the administration of a fatty meal, B one hour after a fatty meal. C and D, postoperative cholecystograms, C taken fifteen hours after the administration of a fatty meal, D one hour after a fatty meal.

Titone¹⁹ reported a series of twenty-five cases in which dyskinesia of the gallbladder was relieved by appendectomy. He presented the preappendectomy and postappendectomy cholecystograms in six instances, demonstrating a return to normal visualization and emptying of the gallbladder following the removal of the appendix. Poenaru-Caplescu²⁰ reported a similar case. He, however, believed that cholecystitis with-

out stones existed prior to appendectomy. Kadrenka²¹ late in 1937 reported a series of thirty-three cases of known appendicitis in which there was normal visualization of the gallbladder but typical symptoms of cholecystitis. In ten of these there was delayed evacuation

Examination.—The patient was thin and poorly developed. The only significant observations at physical examination were abdominal tenderness over the iliac colon and in the right lower quadrant, over the cecum. The iliac colon was tubelike, firm, tender and easily movable under the palpating hand. A cholecystogram showed a large hypertonic gallbladder with good concentration but a marked delay and incomplete evacuation after a fatty meal. There was no evidence of lithiasis (fig. 1 A and B). A gastrointestinal series showed the complex of duodenal irritation with marked diverticular pouching of the duodenum. There was a suggestion of a small erosion in the duodenal pouching. The likelihood of chronic appendicular thickening was observed.

The diagnosis was (1) functional disorder of the biliary tract or dyskinesia of the gallbladder, reflex in type, (2) diverticulum of the duodenum, (3) spastic colon and (4) chronic appendicitis.

Clinical Course.—Between November 1935 and November 1937 the treatment consisted of the use of (1) a modified Sippy diet, low residue, with intermediate feedings, (2) belladonna and phenobarbital, (3) alkalis and (4) olive oil given by mouth. With this regimen there was a distinct improvement in that the symptoms became less severe and the attacks of pain occurred less frequently. In view of the persistent tenderness in the right lower quadrant and over the iliac colon the patient

Fig. 2 (case 2).—A and B, preoperative cholecystograms, A taken fifteen hours after the administration of dye and B one hour after a fatty meal. C and D, postoperative cholecystograms, C taken fifteen hours after the administration of dye and D one hour after a fatty meal.

of the dye after a fatty meal. Relief was secured by appendectomy. There is then some evidence of a clinical syndrome of definite reflex spasm of the biliary tract secondary to appendicitis.

We are presenting three cases of dyskinesia of the gallbladder in which the removal of a diseased appendix has resulted in the relief of the dyskinesia. This is evidenced by the relief of symptoms, i. e. colic, nausea, diffuse discomfort, distention and vomiting; by a postoperative cholecystogram showing normal visualization and normal emptying of the gallbladder, and by biliary drainage showing a normal response to magnesium sulfate and olive oil.

REPORT OF CASES

CASE 1.—History.—A. P., aged 31, who presented himself for treatment Nov. 1, 1935, by courtesy of Dr. Bernard Marraffino of New York City, had had cramplike and nonradiating pain in the right upper quadrant for four years. For the past two months it had been of greater severity. There was never any nausea or vomiting, but occasionally belching and sour eructation occurred after meals. The symptoms were not related to any particular type of food. The pain had always begun about ten minutes after each meal and lasted for a half hour. The patient had had influenza seventeen years before but no other serious illnesses and no operations. He was married and had one child, aged 3 months, who was living and well.

Fig. 3 (case 3).—A and B, preoperative cholecystograms, A taken fifteen hours after the administration of dye and B one hour after a fatty meal. C and D, postoperative cholecystograms, C taken fifteen hours after the administration of dye and D one hour after a fatty meal.

was advised to have his appendix removed with the hope that this was the source of the reflex disturbance.

Appendectomy was performed in November 1937. On exploration of the abdomen, the gallbladder was seen to be distended, enlarged and thin walled. There was no evidence of chronic inflammation or stones. The gallbladder emptied on moderate pressure. A diverticulum of the duodenum was found in the

21. Kadrenka, S.: Appendix: Functionally Controlled Distant Symptoms, *Fortsch. a. d. Geb. d. Röntgenstrahlen* 56: 67-75 (July) 1937.

second portion. The appendix was bound down and thickened but was without evidence of an acute inflammation. The pathologic diagnosis was chronic appendicitis, probably recurrent subacute attacks.

For the nine months of follow-up after appendectomy, the patient felt only slight momentary pain in the right lower quadrant on two occasions, three months and six months postoperatively. He at no time had pain in the upper part of the abdomen. Belching and sour eructation had disappeared. Moderate tenderness over the iliac part of the sigmoid flexure persisted. No medication was prescribed. A cholecystogram, made eight months postoperatively revealed normal visualization and normal emptying of the gallbladder (fig. 1 C and D). Biliary drainage was not done.

CASE 2.—History.—R. A., a married woman aged 34, who presented herself for treatment in the gallbladder clinic Nov. 17, 1937, had had cramplike pain throughout the upper part of the abdomen for four weeks. The pain, which radiated to the right scapula, was paroxysmal, with remissions. Nausea, vomiting and distention accompanied it. One attack of definite colic occurred during this period. No food idiosyncrasy was noted. The patient had an indefinite history of indigestion for the past seven years but no serious illnesses, no operations and a normal menstrual history. She had two children, aged 14 and 9, both of whom were living and well.

Examination.—Physical examination gave essentially negative results except to reveal slight tenderness in the right subcostal area and in the right lower quadrant. A cholecystogram taken at St. Vincent's Hospital by Dr. W. W. Maver showed an organ normal in size, with a fair concentration of dye, which emptied only about one half its contents in response to food stimuli. There was no evidence of lithiasis (fig. 2 A and B). A gastrointestinal series showed abnormal spasticity at the pylorus with delayed gastric evacuation. At twenty-four hours all the meal had passed into the colon. There was a redundant loop of proximal transverse colon which overlay the ascending colon and appeared to be more or less fixed in this position.

Duodenal drainage yielded bile containing 1,000 mg. of bile salts per hundred cubic centimeters. (A bile of Lyon)²² after stimulation with magnesium sulfate 2,000 mg. of bile salts (light colored B bile) and after the administration of olive oil 3,000 mg. of bile salts (dark B bile). No crystals or pus cells were present. Cultures of all three specimens of duodenal bile were negative. A gastric specimen taken during fasting showed a value for free hydrochloric acid of 18.

Chemical examination of the blood disclosed 128 mg. of cholesterol and 61 cholesterol esters per hundred cubic centimeters, an icterus index of 7.8 and negative direct and indirect Van den Bergh reactions.

The diagnosis was reflex dyskinesia of the gallbladder associated with hypertonic hyperacidity of the stomach.

Clinical Course.—The patient was given alkalis, belladonna and phenobarbital. Drainage of the biliary tract was continued at intervals of three weeks. There was moderate improvement in the associated symptoms of nausea and distention. The pain continued intermittently.

April 13, 1938, the patient had increased, knifelike pain, especially in the right lower quadrant, with nausea and vomiting. Examination revealed definite McBurney point pain, rebound tenderness and right rectus spasm. An appendectomy performed April 14 revealed a suppurative process involving the appendix from its base to the tip. The gallbladder was slightly hypervascularized but free from adhesions. The foramen of Winslow and the gastroduodenal segment were normal. The pathologic diagnosis was acute phlegmonous appendicitis in an appendix showing results of previous inflammation.

During the six months of follow-up the patient had a remarkable subsidence of her gallbladder symptoms with only occasional belching and mild distress in the lower part of the abdomen. She continued the use of belladonna and a diet low in calories and fat. A cholecystogram made six months after operation showed normal visualization and normal emptying (fig. 2 C and D). Biliary drainage indicated normal function

of the gallbladder, with 5,000 mg. of bile salts per hundred cubic centimeters after the administration of magnesium sulfate and 4,000 mg. after olive oil.

CASE 3.—History.—M. G., a married woman aged 45, who presented herself for treatment in the gallbladder clinic Dec. 1, 1937, had had colicky pain in the right upper quadrant for three years. The attacks were sudden, severe and of three or four hours' duration. They occurred once a month, accompanied by nausea, vomiting and distention. Slight intermittent pain with distention was present between attacks. The history was essentially irrelevant, there having been no previous illnesses, no operations and a normal menstrual history. The patient had five children between 15 and 26, all living and well.

Examination.—The patient was underweight but well developed and not apparently ill. Examination gave essentially negative results except to demonstrate slight tenderness in the right upper quadrant. A cholecystogram revealed a gallbladder which apparently functioned fairly well, was hypertonic and showed delay in emptying (fig. 3 A and B).

Duodenal drainage disclosed that a gastric specimen taken during fasting had a value for free hydrochloric acid of 8.5. The duodenal bile, A bile of Lyon, contained 1,500 mg. of bile salts per hundred cubic centimeters after the administration of magnesium sulfate 3,000 mg. of bile salts and after olive oil 5,000 mg. of bile salts. Occasional calcium crystals were seen. The cultures were negative.

Chemical examination of the blood revealed 209 mg. of cholesterol and 112 cholesterol esters per hundred cubic centimeters, an icterus index of 4.4 and negative direct and indirect Van den Bergh reactions.

The diagnosis was (1) mild hypertonic reflex disturbance as evidenced by a distended hypertonic gallbladder with delayed emptying and (2) possible chronic appendicitis.

Clinical Course.—The patient was given frequent feedings and also phenobarbital and belladonna. She gained weight and had a distinct decrease in symptoms until Feb. 23, 1938, when she had severe pain in the right lower quadrant for two days, with nausea and vomiting. Examination revealed pain and tenderness in the right lower quadrant with slight rigidity. She was admitted to the hospital with a diagnosis of acute appendicitis.

An appendectomy was performed immediately and disclosed that the appendix was covered with fibrinoplastic membrane. There was no evidence of gross perforation, though clear reactive fluid was present. The gallbladder was hypervascularized but without adhesions and emptied readily. A strawberry type of gallbladder without calculi was suggested. The pathologic diagnosis was acute phlegmonous appendicitis in an appendix showing results of previous inflammation (reduction of lymphoid tissue and scarring).

During the seven months following appendectomy, the patient improved remarkably. The attacks of gallbladder disturbance nearly disappeared, and their severity was eliminated. The patient still had slight nausea. A cholecystogram made four months after the appendectomy revealed a functionally competent gallbladder with normal emptying (fig. 3 C and D). Duodenal drainage indicated a normal gallbladder having a concentration of bile salts of 6,000 mg. after the administration of magnesium sulfate and 4,000 mg. after olive oil. Occasional cholesterol crystals were found. All cultures were negative.

COMMENT

A diagnosis of dyskinesia of the gallbladder was made in each case on the basis of (1) irregular occurrence of symptoms referable to the upper part of the abdomen which were primarily those of indigestion, as well as colicky pain; (2) a cholecystogram revealing no evidence of true cholecystitis (failure to concentrate the dye) or lithiasis but a delay in evacuation of the dye, and (3) the results of biliary drainage (in cases 2 and 3), which revealed evidence of spasm at the sphincter of Oddi with abnormal response to drainage stimuli.

Antispasmodics and sedatives in each instance gave some relief from acute pain but did not relieve the asso-

22. The Aldrich-Bledsoe and the Reinhold-Wilson method of bile salt determination were used in the cases presented.

OBSTETRIC AUDIT—RUNNELS

JOUR. A. M. A.
JULY 29, 1939

ciated symptoms of nausea, vomiting, distention and belching.

Operation in each instance revealed no macroscopic evidence of cholecystitis. The appendix was acutely diseased in two instances, with evidence of longstanding chronic infection. In case 1 the appendix was chronically diseased. The relief from pain in the right upper quadrant and from the associated symptoms of distress, nausea, vomiting and distention which followed appendectomy is evidence of the probable relationship which existed between the disturbance in the appendix and the reflex spasm in the biliary tract. This clinical evidence was further substantiated in all three cases by normal results of postoperative duodenal drainage and a totally normal postoperative cholecystogram.

CONCLUSION

The reflex origin of dyskinesia of the gallbladder may be found in a chronically diseased appendix. Such a relationship seems to have been demonstrated in the three cases presented in this paper.

303 East Twentieth Street.

AN OBSTETRIC AUDIT

SCOTT C. RUNNELS, M.D.
Secretary of the Hospital Obstetric Society of Ohio
CLEVELAND

In recent years American obstetrics has been severely criticized. Certain of the criticisms have been justified. The compilation by the Children's Bureau¹ of the maternal mortality rates for the year 1929, which showed that the United States stood third from the bottom among the nations reporting to the International Health Office, was indeed discrediting; even making allowances for some differences in the methods of reporting, this country's record is bad. Two nations, Chile and Scotland, had rates that were higher than that of the United States, and Norway's rate of 3.0

TABLE 1.—United States Maternity Mortality*

* From a United States Bureau of the Census release dated Jan. 13, 1939

compared unfavorably with the 7.0 of the United States. In 1929 if the United States rate had been the same as Norway's there would have been 9,000 fewer maternal deaths in this country.

However, unsatisfactory as the situation was, it was not as bad as many of the articles appearing in both lay and professional journals pictured it. A statement often quoted is that 22,000 women die annually in

childbirth.² While that was true twenty years ago, when both the birth rate and the puerperal death rate were higher, the fact is that in 1937 10,769 deaths were due to the puerperal state. Again, the statement has been made³ that American hospitals are unsafe places in which to have a baby born. The facts will be analyzed later, but suffice it to say that the statement should not have been made to apply to all hospitals. The

much publicized statement⁴ that preventable sepsis was rampant is to say the least a flagrant misrepresentation. While there is much that can and should be done to improve American obstetrics, the situation is not as unfavorable as both the public and the profession have been led to believe.

During the years in which this barrage of criticism was descending, forces were at work which were making the criticism less and less justified. Progress in lowering the maternal death rate and in improving obstetric practice has gone steadily forward (chart 1). Since 1920, except for four years, in only one of which (1928) was the rise marked, there has been a constant fall in the maternal mortality rate. Since 1929 this fall has been accelerated, and for the year 1937 it was notable. The decrease in the rate from 5.68 in 1936 to 4.89 in 1937 was 13.9 per cent, which was greater than the decrease in the four previous years combined (6.41 in 1932). From 1929 through 1937 the fall in the maternal mortality rate was 30 per cent, and more than a third of it took place in 1937. Further, in 1938 the total number of puerperal deaths in Ohio, the only state for which I have means at present of knowing the record for 1938, fell to 425 from 490 in 1937, a decrease of 14.3 per cent.

Comparing the reduction in maternal mortality with that of the general mortality, one will see that the puerperal rate has fallen much more sharply. The decrease in the general mortality from 1929 to 1937 was 7 per cent, while the decrease in the puerperal death rate was 30 per cent for the same period.

Turning to the components of maternal mortality, one finds nine major causes the records of which are here compared for the last five years (table 1). The general decrease is gratifying but not uniform. It will be noted that there has been a decrease in the number of hemorrhagic deaths of only 1.5 per cent, while the mortality has decreased for toxemia 14.2 per cent, accidents 18.7 per cent, abortions 21.1 per cent and puerperal septicemia 23.6 per cent.

infection.

Further analyzing these deaths, one finds that abortions and ectopic pregnancies caused a considerable proportion. These two causes, together with a small group of miscellaneous reasons for maternal death early in the pregnancy, are in no sense dependent on the obstetric management. The obstetrician does not come into the obstetric department. In fact if the hospital is a specialized maternity hospital they do not enter it at all. The general hospital, then, will have a higher puerperal death rate because it accepts this class of case. Many general hospitals not handling obstetric patients at all have a high puerperal death rate because of them. Deaths from abortions and ectopic pregnancies therefore are not a proper charge on obstetrics. There should be an additional classification, the obstetric death rate, determined from deaths attributable to the obstetric care, those occurring subsequent to the time of viability of the child, the deaths due to abortion, ectopic pregnancy and other nonobstetric conditions of early pregnancy being excluded. Deaths due to abortion

are a proper component of the puerperal death rate, which denotes the risk of pregnancy, but not of the obstetric death rate, which denotes the risk of delivery. Taking the figures from three studies that have been made⁵ and the census bureau figures for the last five years (table 2) and excluding the deaths from abortion and ectopic pregnancy, one finds that the obstetric death rate is somewhat less than three fourths of the puerperal death rate.

Further, since abortion is not a part of the obstetric risk, the sepsis that is incident to the abortion should not be included with the infective conditions that arise at the time of delivery. Almost half of the deaths commonly classified as due to puerperal septicemia are this cause give the impression that sepsis causes many more obstetric deaths than it actually does. If there had been a general understanding of these facts, so much criticism would not have been leveled at obstetric infection.

OBSTETRIC AUDIT—RUNNELS

Jour. A. M. A.
July 29, 1939

Studying the puerperal deaths as they occur throughout the United States, one finds a great variability in different localities (chart 2). In 1937 the maternal mortality for the states ranged from a low of 25 per

other words, about one seventh of the cities have a very creditable record and one ninth have a poor one. Comparing the percentage of hospitalization with the puerperal death rates, one sees that in almost every instance in which the rate is good the rate for hospitalization is high, averaging 76.7 per cent, while in the instances in which there is a poor puerperal death rate the percentage of hospitalization, except in a few cases, is low, averaging 60.2. In the cities having a large number of births the percentage of hospitalization tends to be either higher and the puerperal death rates lower and the experience from year to year has a less wide variation.

No specific study has been made of the improvement in the city rates because of the great variations that occur in some of them, at times because of the relatively small number of cases in any year and again because of the markedly different conditions that exist among the cities. Particularly deviating from the normal are those cities that have large surrounding areas from which patients are drawn to the metropolitan hospitals. In some cities, Columbus, Ohio, for example, a high percentage of the puerperal deaths occur in the suburbs and the city's rate is thus improved. A case in point is Milwaukee, with the city-

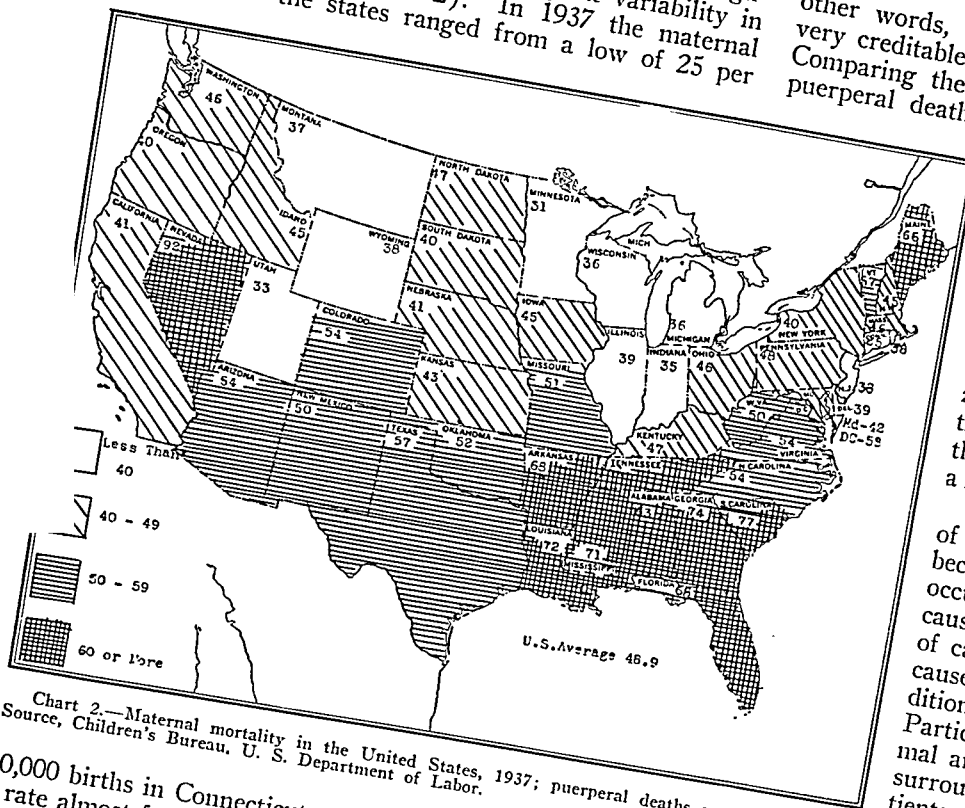

Chart 2.—Maternal mortality in the United States, 1937; puerperal deaths per 10,000 births.
Source, Children's Bureau, U. S. Department of Labor.

10,000 births in Connecticut to a high of 92 in Nevada, a rate almost four times as great. Twelve of the states had a rate below 40 and ten a rate above 60.

The improvement made in the past six years is significant (chart 3). Since there may be incidental variations in any one year's rate that might make comparison unfair, the average rate for each state for 1930 and 1931 is compared with the average rate for 1936 and 1937. There was a fall of 22.3 per cent for the entire United States in this period. One fourth of the states had a drop of more than 25 per cent, while one fourth had a drop of less than 15 per cent. Some of the states with the lowest rates in 1937 did not show a great decrease because their rates had been relatively low for a considerable period, while some of the states whose rate was still high showed marked improvement.

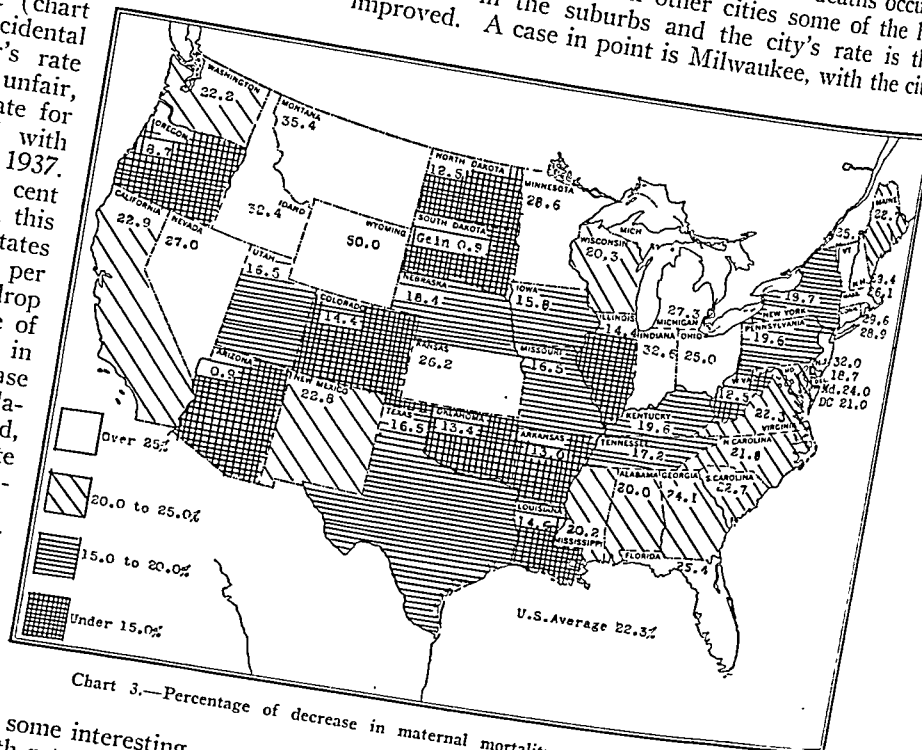

Chart 3.—Percentage of decrease in maternal mortality, 1930-1931 to 1936-1937.

The cities have an even greater divergence in maternal mortality. Eighty-one cities in the United States with a population of more than 100,000 had more than 2,000 births in 1937 (table 3). Studying the figures for this group of cities for the past three years, one can make some interesting deductions. Of the 243 puerperal death rates, fifty, or 20.6 per cent, are below 4 and forty-one, or 16.9 per cent, are above 8 deaths per thousand live births. Eleven of the cities have rates below 4 more than once, and nine have rates above 8 more than once. In

county hospital in Wauwatosa outside the city registration area. In other cities, such as Boston, many patients receiving the best obstetric care live outside the city area but are delivered in the city hospitals. These and other factors affect the city rates in varying degrees and make comparisons confusing and unfair.

The contribution of cities to the puerperal death rate as compared with that of rural areas is worthy of note (chart 4). The puerperal mortality of the cities varies from 10 to 20 deaths per 10,000 births in excess of that of rural areas. The contribution of each group to the total is about equal, 5,876 deaths in cities to 4,893 in rural areas in 1937. However, it will be noted that in 1920 the difference was less than it was in subsequent years, and if the chart had been carried into previous

Chart 4.—Puerperal death rate in cities with a population of more than 10,000 as compared with the total rate and the rural rate; source, Bureau of the Census, March 29, 1939, vol. 7, No. 29, p. 108.

years this difference would have diminished even more. This increase in the preponderance of urban puerperal deaths can be attributed to the increase in the prestige of the urban hospital during that period and to the fact that patients in a serious condition were taken to the city hospitals in a final effort to save life. Again, in 1937 this divergence between the urban and rural rates lessened, and this reduction can be explained by the improvement that has recently occurred in the puerperal rates of hospitals.

This understanding of the reason for the increase in the number of puerperal deaths in cities, that is, the influx of nonresident patients who are taken to the city hospitals on account of the development of some serious condition that makes care in their home environment inadequate, points the way to the explanation of another comparison that has long been confusing. The hospital puerperal death rate is larger than the home rate and many have unthinkingly criticized the hospital because of this fact. In the Cleveland study of puerperal deaths, 84 per cent of the women who died in hospitals were found to have had a known pathologic condition on entrance. It has become increasingly true that if serious complications develop during labor at home the patient is taken to the hospital. A great number who would have died at home are saved by the efficient care available in the hospital. However, the hospital death rate is and will continue to be augmented as long as women are rushed to the hospital as a last resort. As more and more women go to well managed hospitals for delivery the ideal will be approached and only the unavoidable deaths will occur.

Returning to the consideration of the obstetric situation in the states, one finds three factors that contribute

to the character of the obstetric care which can be accurately evaluated. These are, in the order of increasing importance, the percentage of nonwhite births, the percentage of care by graduate physicians and the percentage of hospitalization of obstetric patients.

The nonwhite births (chart 5) are largely in the extensive Negro population in the South and the smaller Indian population in the Western states, with a sprinkling from the Asiatic population in the Pacific states. One fourth of the states have less than 2 per cent and one fourth more than 10 per cent of nonwhite births. This factor certainly has a bearing on the high obstetric rates in the South; however, since nonwhite births comprise only one eighth of the total births and since for one half of the United States less than one birth in twenty is not white, this factor has no great effect on the general puerperal rate (chart 6). Not only does the general curve remain close to the curve for the white race, but severe fluctuations in the "other race" curve are not reflected in the general curve.

The percentage of women delivered by graduates in medicine (chart 7) is somewhat more significant. It demonstrates that the midwife problem and that of the mother who has no attendant are not potent factors in the puerperal death rate in the greater part of the country. But it will be noted that in some states in the South midwives deliver many of the women, and this factor probably has considerable significance in the poor record of these states. However, these are the states in which all the detrimental factors accumulate. In one fourth of the states all but 0.5 per cent of women in labor are under the care of a graduate in medicine; in another fourth all but 2 per cent are thus attended. Then, at the other extreme, there are ten states in

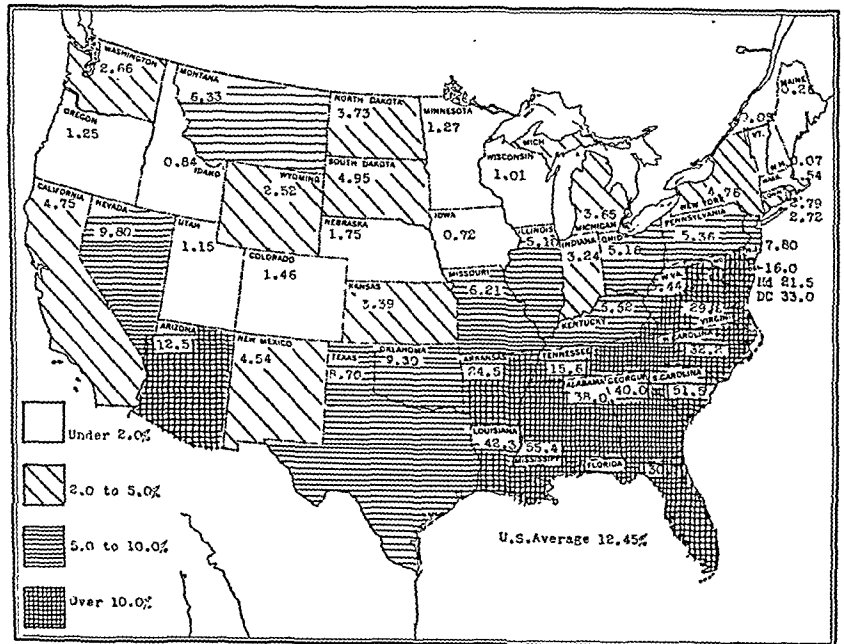

Chart 5.—Percentage of nonwhite births, 1937.

which one fourth of the women do not have medical care.

The third measurable factor is of greater significance (chart 8). The percentage of births that occur in hospitals comes closest to indicating the position a locality will have in its maternal mortality standing. One fourth

of the states have more than 60 per cent of their births in hospitals, while the last fourth have less than 25 per cent in hospitals. The average for the United States in 1937 was 44.8 per cent. Comparing the percentage of hospitalization in the various states for 1937 (chart 8)

impossible with less than an average occupancy of four patients. In constructing chart 9 the number of births in the next smallest group was superimposed on the number of births in the smallest group. In 1938, for example, there were 135,000 births in hospitals having less than twelve and one-half births a month and 154,000 births in the next group, having more than twelve and one-half births a month; hence the total charted was 289,000. This process was repeated for

Chart 6.—The trend of maternal mortality by race, 1920-1937, puerperal deaths per 10,000 births; source, Bureau of the Census, March 29, 1939, vol. 7, No. 29, p. 112.

with the maternal mortality rates in the same states for the same year (chart 2), one makes the striking discovery that twenty-two states fall in the same category on the two charts and that only three states show any marked deviation. This extent of parallelism in the two charts is the strongest possible argument in establishing the fact that the extent of hospitalization determines the incidence of maternal mortality.

The importance of the hospital as the major factor in the control of maternal mortality is further evidenced by the great increase that has occurred in the hospitalization of the obstetric patient. Unfortunately, accurate statistics showing this trend are available only for the last few years, since the annual publication of the survey of hospitals by the American Medical Association (chart 9). Obstetric hospitals may be divided into five groups according to the number of patients handled: (1) those that have more than 100 births a month, or more than 1,200 a year; (2) those that have more than fifty births a month, or more than 600 but less than 1,200 a year; (3) those that have more than twenty-five births a month, or more than 300 but less than 600 a year; (4) those that have more than twelve and one-half births a month, or more than 150 but less than 300 a year, and (5) those that have less than twelve and one-half births a month, or less than 150 a year. The figure of twelve and one-half births a month was chosen as the minimum because practical isolation of the obstetric department is

TABLE 4.—Puerperal Mortality in Ohio Hospitals

Having less than 150 births a year	1937	66	4,804	78	15.10
	1938	73	3,886	73	18.80

each succeeding group, so that the top line gives the total births for all hospitals for each of the four years considered.

Studying these figures, one sees some interesting trends: 1. The total number of births in hospitals has increased 321,000, or 46.5 per cent, in four years. This tendency has been accelerated in the past two years, the increase having been 101,000, or 14.5 per cent, in 1937 and 91,000, or 13.1 per cent, in 1938. 2. The

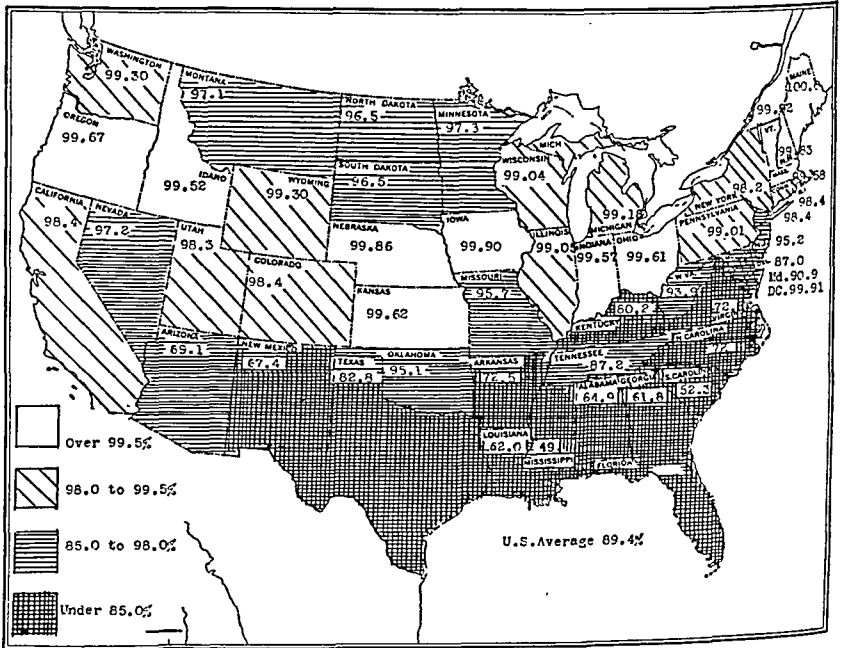

Chart 7.—Percentage of women delivered by a physician, 1937.

increase has been almost entirely in the three groups of larger hospitals. In fact, in the group having between fifty and 100 births a month the number has more than doubled in the four years, having increased from 134,000 in 1934 to 290,000 in 1938. On the other hand, hospitals having less than twelve and one-half births a month had fewer births in 1938 than they had in 1934, 135,000 as compared with 143,000.

In studying the number of hospitals in each group according to the number of births, one observes at once that the total number of hospitals has made but slight increase in the four years, rising from 3,892 to 4,022,

American College of Surgeons,⁷ including the provision that the chief of the obstetric division of a hospital must have supervision over all patients, both staff and private, in the institution, have added force to the movement. Most recently the United States Bureau of Maternal and Child Health¹ went on record as recommending "that the enforcement of the obstetric code of each hospital must be under the supervision" of the obstetric director of that hospital and that "each hospital shall secure the signature of each physician having the privilege of obstetric practice in that hospital to" a pledge committing that physician to consultation whenever, in the opinion of the hospital authorities, complications have arisen.

Such provisions have definitely drawn the line between a hospital which is obstetrically safe and one that is a hazardous place for the expectant mother. In summary, there are two types of safeguard that are fundamental:

1. That the hospital maintain proper obstetric regulations, especially isolation of the department, as outlined by the American Hospital Association.
2. That the hospital have a proper staff organization, including a chief, with power to enforce consultation for all questionable conditions.

or 4.1 per cent. However, the significant thing is the increase in hospitals handling a large number of obstetric patients. Hospitals handling more than 100 births a month increased from sixty-four to 103, or 61.0 per cent, and hospitals handling from fifty to 100 births a month more than doubled, increasing from 168 to 355, percentage increases that closely approximate the increase in births for the same groups for the same period. At the other end of the scale, hospitals caring for less than twelve and one-half births a month decreased from 2,632 to 2,252, or 14.4 per cent, in the four years. The implication of these figures is that hospitals that were small, obstetrically speaking, in 1934 rapidly expanded in these four years. The enormous increase in the hospitalization of the obstetric patient is, it goes without saying, the fundamental fact from which all these changes spring. In an increasing number of hospitals the care of obstetric patients is a growing proportion of the work.

Perhaps in no small measure responsible for this increase has been the growing sense of responsibility felt by hospitals for the character of the work being done within their walls. In many localities the hospitals have used various methods to supervise the obstetric department. The "standards" adopted by the Hospital Obstetric Society of Ohio, the recommendations of the Philadelphia County Medical Society and the regulations of the Chicago Board of Health and the Maternal Welfare Committee of the Chicago Gynecological Society are but a few of the efforts to raise the standards of obstetric practice and to increase the safeguards surrounding each patient. More recently the obstetric standards set up by the American Hospital Association⁶ and the pronouncement last year by the

7. MacEachern, M. T.: Program of American College of Surgeons for Maternal Care in General Hospitals, *Am. J. Obst. & Gynec.* 35:535 (March) 1938.

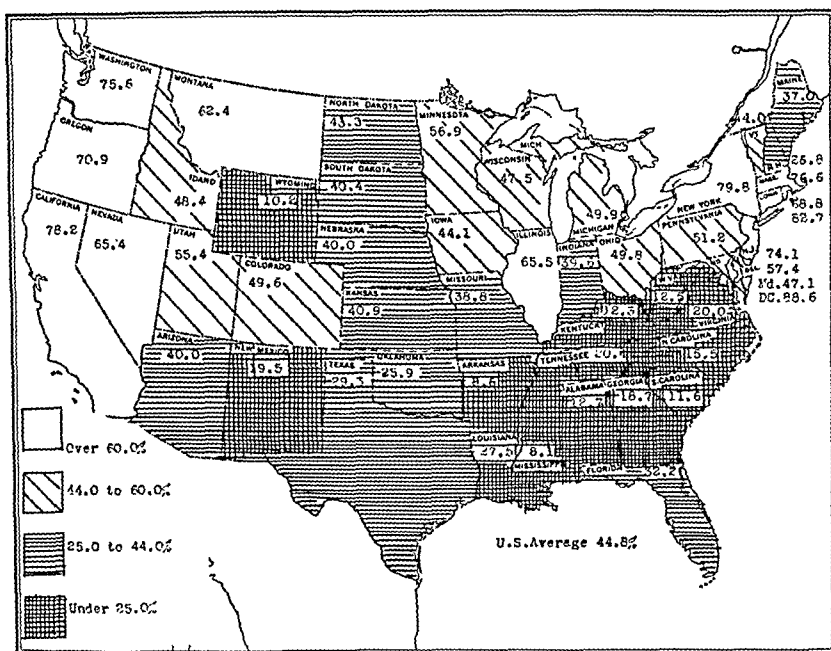

Chart 8.—Percentage of births in hospitals, 1937.

Chart 9.—Cumulative curves for 1934-1938.

A striking example of the value of these criteria is shown by a survey of Ohio hospitals for the years 1937 and 1938 (table 4). The facts stand out so clearly that

it seems almost unnecessary to comment on them. Approved hospitals are the safest possible places for delivery, and as the regulations discussed become more effective these hospitals are becoming safer. Unapproved hospitals do not have a commendable record, and hospitals that have too small an occupancy to maintain isolation are a distinct menace. The figures point to the conclusion that unless a hospital can meet the approved standards for obstetric care it should not take obstetric patients. The group of small hospitals, as previously shown, is rapidly diminishing the country over, and reports such as the Ohio survey only emphasize the desirability of such an elimination. Only hospitals that can meet the standards of the American Hospital Association and the American College of Surgeons are proper institutions for the obstetric patient.

CONCLUSIONS

1. United States obstetrics has been making decided and accelerated strides in the reduction of maternal mortality.
2. The hospitalization of obstetric patients has markedly increased.
3. Supervision by the hospital of the character of the obstetrics practiced within its walls and the enforcement of early consultation in the case of abnormal labor has become recognized as essential.
4. As the births of the United States increasingly occur in well organized hospitals and come increasingly under the supervision of trained obstetricians, maternal mortality and morbidity will continue to improve.
5. If obstetric conditions were as favorable over the entire United States as are those existing today in a quarter of the country, there would be an annual saving of 2,500 lives.

Clinical Notes, Suggestions and New Instruments

ACTINOMYCOSIS OF THE GALLBLADDER

RALPH C. SULLIVAN, M.D.; NICHOLAS T. FRANCONA, M.D.
AND
ALEX B. RAGINS, M.D.
CHICAGO

Isolated actinomycosis of the gallbladder has been reported in only a few instances. Mayo-Robinson¹ reported the first case in the literature in 1905. His case is of great interest in that it was followed up for four years, during which time there was no recurrence of symptoms. Since then Good² has mentioned two cases in which the primary lesion was found both in the gallbladder and in the appendix.

In view of the rarity of this lesion, we thought it worth while to report this case.

REPORT OF CASE

History.—Mrs. A. H., a middle-aged white woman, was admitted to the Cook County Hospital May 30, 1938, with a tentative diagnosis of acute cholecystitis. On questioning, the patient stated that for the last twenty years she had had attacks of pain in the upper part of the abdomen which were attributed to gallbladder trouble. The attack prior to the one for which she was admitted occurred about two years before. It was characterized by sharp, steady pains, which were felt in the upper part of the abdomen and radiated to the back. These pains often started after the ingestion of fatty or fried foods.

From the Departments of Surgery and Surgical Pathology, Cook County Hospital.
1. Mayo-Robinson, A. W.: Actinomycosis of the Gallbladder, Tr. M. & Chir. Soc., London 88: 225, 1905.
2. Good, L. P.: Actinomycosis of the Abdomen, Arch. Surg. 22: 307 (Feb.) 1930; Actinomycosis of the Thorax, ibid. 21: 786 (Nov.) 1930.

Between attacks the patient was quite free from pain, although she would belch frequently.

The present attack began Friday May 27, following a meal of ham and cabbage. At first the pain was dull and steady, letting up somewhat the following morning after a number of anodyne tablets had been taken. The next day the pain in the right upper quadrant became very sharp and steady. It continued until the following morning, when the patient entered the hospital for treatment.

On physical examination the patient was well developed and was suffering severe pain in the abdomen, appearing acutely ill. The pulse was 118 and regular. Respirations were 28 a minute and the blood pressure was 140 systolic, 75 diastolic. The temperature was 101.8 F. The pupils were contracted and reacted to light and in accommodation. The lips were pale and the teeth were in poor condition. The chest was resonant throughout, and expansion was equal on the two sides. The breath sounds were clear. The heart was of normal size and no murmurs were heard. The mammae were normal. The abdomen was obese with distinct striae. Marked tenderness and rigidity were noted over the right upper quadrant but was less marked over the rest of the abdomen. Rebound tenderness was elicited over the entire abdomen. The liver was two finger-

Fig. 1.—Gallbladder showing the grayish white membrane adherent to the mucous membrane in which the actinomycetes were found. This is particularly marked in the fundus of the gallbladder.

breadths below the right costal arch. The peristaltic rate was 30 a minute. Vaginal examination was essentially negative except for a lacerated cervix and a firm retroflexed uterus. The uterine adnexa were normal. Rectal examination was negative. In view of these clinical observations a diagnosis of acute cholecystitis and cholelithiasis, probably associated with an old hepatitis, was made.

Laboratory examinations revealed hemoglobin 80 per cent, erythrocytes 4,360,000 and leukocytes 22,750. The Kahn reaction of the blood was negative. Examination of the stool revealed blood 2 plus on one occasion. The urine showed albumin 1 plus and a few polymorphonuclears. A Graham Cole visualization of the gallbladder was negative.

In view of the persistent pain and the failure to respond to medical treatment, the patient was transferred to the surgical department for removal of the gallbladder. The patient was operated on by Drs. Sullivan and Francona June 10. A Judd incision was made to expose the gallbladder. An impacted stone was dislodged from the cystic duct through an incision of that duct. The cystic duct and artery were then separately ligated and the gallbladder was removed.

Pathologic Examination.—The specimen consisted of a gallbladder, previously opened, which measured 8 cm. in length and 7 cm. in circumference. The serosa was injected, a purplish gray, and the wall was thickened up to 8 mm. The mucosa was a purplish red and in places was covered by fairly large firmly

adherent gray-white plaques (fig. 1). The lumen was filled with numerous faceted stones measuring up to 8 mm. in diameter. A section was taken through the entire thickness of the wall, including the gray-white plaque adherent to the mucosa.

Fig. 3.—Section showing the characteristic colony of the actinomycetes in the mucous membrane of the gallbladder. Gram-Weigert stain; $\times 1,000$.

A section of the gallbladder stained with hemalum and eosin revealed a markedly thickened wall infiltrated with many lymphocytes and large mononuclear cells, some of which were multinucleated. The arterioles and capillaries were dilated and the walls of the former were moderately thickened. In places the endothelium showed a moderate hypertrophy and hyperplasia. The mucous membrane was replaced by a necrotic

membrane heavily infiltrated with many polymorphonuclear leukocytes, large mononuclear cells and a few lymphocytes. In one portion of the membrane, near the surface, were small, irregular granular, bluish staining areas surrounded by a single row of polymorphonuclear leukocytes. On staining a section with Gram-Weigert stain the granular areas were found to be composed of a filamentous gram-positive structure (fig. 2). The filaments were granular with slight clubbing of the free ends (fig. 3). In addition, single filaments were seen surrounded by polymorphonuclear leukocytes and large mononuclear cells (fig. 4).

COMMENT

The diagnosis of the actinomycotic infection of the gallbladder was not made grossly, and therefore we were unable to cultivate the ray fungus. However, the microscopic study showed distinct ray-shaped clusters and more loosely arranged branched slender mycelia, which may be classified as *Cohnistrepotrix israeli* because of the typical radiating colonies found in the necrotic membrane. The actinomycotic infection of the gallbladder in this case was most likely due to a retrograde extension of the infection from the gastrointestinal tract into the gallbladder. This is substantiated by the fact that the ray fungus was found only on the surface of the mucosa and in no

Fig. 4.—Section of the gallbladder mucosa showing single mycelial threads of the actinomycetes surrounded by mononuclear cells and polymorphonuclear leukocytes. In addition is seen a small ray fungus colony in poor focus. Gram-Weigert stain; reduced from a photomicrograph with a magnification of 1,000 diameters.

place were we able to find the actinomycosis in the wall of the gallbladder or in the lumen of the blood vessels.

The patient, seen seven months after the cholecystectomy, stated that she had been completely alleviated of pain and the symptoms experienced prior to her operation and that the wound had completely healed. Mayo-Robinson in his report states that the patient was well for four years following a cholecystostomy.

As to the primary focus of infection in our case, several possibilities must be considered: First, the carious teeth; Klinger³ states that the organism is an obligatory parasite, i. e. a permanent inhabitant of the mouth. Shapiro,⁴ quoting Sanford and Magath, and Zininger, stated that the primary source of infection in 60 per cent of the cases of actinomycosis has been carious teeth. The lungs too may be a primary source of infection, as found in 14 per cent of the cases of actinomycosis. The intestine is found to be a primary source in 18 per cent of the cases.

Our patient had poor teeth, and it is possible that the primary infection may have been in the teeth or in the duodenum. No other actinomycotic lesions were found in the patient.

3. Klinger, in Lehmann, K. B., and Neumann, R. O.: *Bacteriology, Especially Determinative Bacteriology*, 2d ed., English translation, edited by R. S. Breed, New York, McGraw-Hill Company, 2: 776, 1931.
4. Shapiro, P. F.: *Pyemic Form*, Arch. Path. 12: 397 (Sept.) 1911.

SUMMARY

In a case of actinomycosis of the gallbladder in a middle-aged white woman, periodic attacks of gallbladder colic had been occurring for the past twenty years. Microscopic examination of the gallbladder revealed colonies of the organisms characteristic of the ray fungus. Following removal of the gallbladder the patient improved and did not experience the subjective symptoms existing prior to the operation. The infection, we believe, was due to a retrograde spread from the intestinal tract, since it was limited to the mucous membrane of the gallbladder.

CONFERENCES ON THERAPY

THE USE OF ANTHELMINTICS

NOTE.—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors.

DR. HARRY GOLD: The conference this morning is on the subject of anthelmintics and the treatment of intestinal parasites. There are several varieties of intestinal worms and many anthelmintic agents. Chapters in textbooks on this subject, if they affect you as they do me, will often leave you with no clear idea what anthelmintics are most effective in the different forms of infestations. Evidence on these matters is very difficult to secure, and the impression is difficult to escape that the shift of interest from one anthelmintic agent to another is sometimes a matter of fashion. It is hoped that the discussion this morning will help to clarify some of the problems. Dr. Travell will begin the pharmacologic discussion.

DR. JANET TRAVELL: This is a list of the helminths which most commonly infest the human intestine, and which one may be called on to treat:

- Cestodes or flatworms: 1. Tapeworms: (a) *Taenia saginata* (beef); (b) *Taenia solium* (pork); (c) *Diphyllobothrium latum* (fish).
Nematodes or roundworms: 2. Hookworms (*Necator* and *Ancylostoma*). 3. Roundworm (*Ascaris*). 4. Pinworm (*Oxyuris*). 5. Whipworm (*Trichuris*).

I have also listed some of the anthelmintic drugs which have come into, and in some instances have gone out of, fashion:

- Thymol.
Beta-naphthol.
Hexylresorcinol.
Other alkyl-hydroxyphenols.
Carbon tetrachloride.
Tetrachlorethylene.
Oil of chenopodium.
Ascaridole (active principle of oil of chenopodium).
Mixtures of oil of chenopodium or ascaridole with either carbon tetrachloride or tetrachlorethylene.
Santonin.
Oleo-resin of aspidium, or extract of male fern.
Pelletierine.
Cusco.
Sap of the fig tree.
Solutions of various astringents and antiseptics for rectal instillation.

Why is there such a long list of drugs and what are the reasons for the confusion existing, as Dr. Gold indicated, as to which is the most effective agent in the treatment of infestation by any one of these parasites?

First, there is difficulty in obtaining good criteria for evaluating effectiveness. One might think that it would be a relatively simple matter to administer a series of these vermifuges to comparable groups of patients and to determine what percentage of each group was cured, which would certainly afford a satisfactory basis for comparison. As a matter of fact, however, this method can be applied practically only to tapeworm infestations. Sanground recently studied several anthelmintics by this technic and found that in tapeworm infestations 4 cc. of carbon tetrachloride cures at least 75 per cent of the patients treated, 4 cc. of tetrachlorethylene only 35 per cent, and hexylresorcinol in total doses of from 1 to 6 Gm. only 29 per cent.

One source of error in determining the percentage of patients cured is that reinfection after treatment may occur, and this possibility makes it difficult to establish the fact as to whether a cure was or was not obtained. In the case of the tapeworms, man usually harbors only the adult form; and the intermediate host, that is, the cow, hog or fish, harbors the larvae. Reinfection, therefore, is usually easily prevented by merely instructing the patient in the importance of thoroughly cooking meat and fish and probably does not introduce any serious error in the evaluation of the results obtained in this infestation. In the case of the other parasites, however, no intermediate host is necessary. The larvae of the hookworm and *Ascaris* must gain access to the soil for certain stages of development, and reinfection with the larvae subsequently takes place either by penetration through the skin in the case of hookworm, or by introduction into the mouth in the case of both of these. It is therefore difficult to control the factors leading to reinfection by these two parasites. As for the pinworm, the entire life cycle takes place within a single human individual. The female migrates to the region about the anus to lay the eggs, which are then introduced into the mouth by way of the fingers. It requires only a few weeks for these larvae to attain adult form in the intestinal tract. Therefore, in the case of this parasite the prevention of reinfection is very difficult and presents a special therapeutic problem necessitating particular attention to rectal hygiene. The whipworm also has its complete life cycle in one individual and is extremely resistant to treatment.

However, the chief obstacle to using the cure rate as a criterion of effectiveness seems to be that a cure is so rarely obtained by safe doses of the anthelmintics in the case of the major infestations, that is, *Ascaris* and hookworm, which involve large numbers of the population and which should therefore offer the most suitable material for investigation. Hence the percentage of worms expelled has been used as the basis for comparing the different forms of treatment. In order to obtain this percentage, one must know both the number of worms expelled and the number remaining in the intestine after treatment. The former figure may be obtained fairly accurately by direct counts, although this is a laborious procedure and does not take into account those worms which may disintegrate before expulsion, and may not include those the expulsion of which may be delayed for as long as ten days. The latter figure, in the case of human beings, is of course based on estimates. These estimates are obtained either by various technics for the counting of ova continuing in the feces after treatment

or by counting the number of worms expelled after a second or "test" treatment given at a fixed interval after the first. Both the counting of worms and the counting of eggs gives only an approximate idea of the number of worms remaining in the intestine, but in addition some anthelmintics depress directly the egg-laying capacity of the parasite without killing it, so that judged by the egg-counting method, the patient may seem to be cured but subsequently the worms recover and ova reappear. It then becomes very difficult to decide whether reinfection has taken place and what percentage of the worms was removed by the treatment. Nevertheless the egg-counting method seems to be the best one available for estimating clinical efficiency. Hall has developed a direct method for evaluating the action of these drugs in experimental animals: he counts the worms expelled after treatment, then kills the animal and counts the worms that remain in the intestinal tract. The *in vitro* method of testing is of course less expensive and permits rapid orientation with respect to a long series of compounds. The most satisfactory test object seems to be the pig ascaris, which was first extensively used by Lamson.

In the choice of a vermifuge we are concerned not merely with the question of which one is the most effective but also with the question of which one is the safest. Let us consider first the toxic effects of one of the more important anthelmintics, carbon tetrachloride.

Carbon tetrachloride has been the most popular drug in the treatment of hookworm since it was introduced in 1922. I think Dr. Smillie, who is here today, was the first to administer carbon tetrachloride to patients, and he was the first to call attention to its toxic effects on the liver and kidneys in a report published soon after its introduction as an anthelmintic, at a time when the earlier clinical reports were exceedingly optimistic.

It is important to realize that occasionally a single ordinary therapeutic dose of this drug may prove fatal to the patient. The dose of carbon tetrachloride is now stated as from 3 to 4 cc. At the outset of its use the doses of carbon tetrachloride commonly prescribed were much larger, from 6 to 15 cc., and doses up to 40 cc. were survived. Leach reported 35,000 cases of hookworm treated with doses of from 6 to 12.5 cc. without serious poisoning, yet deaths have occurred in adults after a single dose of from 1.5 to 3 cc., and in children after less than 1 cc. At the present time the risks of poisoning with carbon tetrachloride are much less than they were ten or fifteen years ago because of the large amount of experimental work which has been done on this drug, so that we are now better informed as to how to use it, both with regard to the precautions to be observed in prescribing it and also with regard to treatment, should poisoning unfortunately occur.

Among the factors which may contribute to a fatal outcome after therapeutic doses of carbon tetrachloride, I will discuss first low calcium reserves. Dogs maintained on a low calcium diet die after very much smaller doses of carbon tetrachloride than when maintained on a high calcium diet. The mechanism of the antagonism between calcium and carbon tetrachloride is not clear, but it has been shown in dogs that the administration of calcium prevents and relieves the symptoms of poisoning and also the signs of disturbed carbohydrate metabolism, causing a restoration of the normal blood sugar level and a lowering of the accumulated blood lactic acid. Calcium does not prevent the rise in blood guanidine, which is seen in carbon tetrachloride poisoning, but is antagonistic to the toxic effects of guanidine. Calcium

has no influence on the pathologic changes in the liver produced by carbon tetrachloride, the damage being about the same whether the animal is given calcium and survives or whether it is not given calcium and dies. It seems that calcium administration merely tides the patient over until regeneration of liver cells can take place, which is fairly rapid and complete. In carbon tetrachloride poisoning the total blood calcium is not materially lowered, but it is believed that there may be a reduction in ionized blood calcium. At any rate calcium is a very effective antidote.

The amount of calcium required for the treatment of carbon tetrachloride poisoning in man is not known exactly. However, when dogs maintained on a low calcium diet are given a fatal dose of carbon tetrachloride, the dose of calcium which has secured survival would be for a man, on an equivalent weight basis, about 1 Gm. of calcium a day by vein, or about 100 cc. of a 10 per cent solution of calcium gluconate, together with 5 or 6 Gm. of calcium a day by mouth. For intravenous injection the calcium salt may be conveniently added to a larger volume of dextrose solution, thus assuring that it is injected very slowly. The oral administration of calcium may be difficult because of persistent vomiting, and absorption by this route is unreliable.

The habitual consumption of alcohol is another important factor, even when no alcohol is consumed with the drug. Alcohol given simultaneously with carbon tetrachloride increases its absorption and toxicity, but I am speaking now of the habitual consumption of alcohol rather than the simultaneous administration of the two drugs. Both alcohol and carbon tetrachloride are known to injure the liver. In addition, it has been shown by Rosenthal in dogs that a small oral dose of alcohol, which of itself causes no demonstrable liver damage, sensitizes the liver to the toxic action of carbon tetrachloride, so that less of the latter is needed to cause death. It is apparently well established that most of the individuals who have died after small doses of carbon tetrachloride were chronic alcoholic addicts, presumably with preexisting liver disease. Chronic alcoholism in man seems to be a clearcut contraindication to the use of carbon tetrachloride.

Meat eating is another factor which has been shown experimentally to cause an acute exacerbation of the symptoms of carbon tetrachloride poisoning and a sharp rise in blood guanidine. Low glycogen reserve, or starvation, appears to decrease the tolerance to the drug. Oils and fats taken simultaneously with the drug cause a more rapid absorption of carbon tetrachloride.

At this point I should like to speak about the effect of oils on the toxicity of the anthelmintic drugs in general. Carbon tetrachloride, tetrachlorethylene and the other halogenated hydrocarbons are the only group of anthelmintic drugs, so far as I know, the toxicity of which is known to be increased by the simultaneous administration of organic oils or fats. It is generally stated that the toxicity of thymol is increased by oils, but this statement is based on a misquotation of the original work by Schultze published in 1915. Schultze concludes that "oils in which thymol readily dissolves greatly increased the dose necessary to kill," that is, reduced its toxicity. That is the statement which is generally misquoted. Hall has also shown in an experimental study that oils reduce the toxicity of aspidium, and the same is known to be true for hexylresorcinol and for oil of chenopodium. This matter is of considerable importance in the selection of a cathartic to be administered very soon after the anthelmintic agent, the choice lying usually between a

saline cathartic and castor oil. It would seem wise in the case of the carbon tetrachloride group that only a saline cathartic, such as magnesium sulfate, be used.

Tetrachlorethylene should logically follow carbon tetrachloride in the sequence of discussion. These substances differ considerably with respect to their toxic effects. Of the two, tetrachlorethylene has been shown to be very much less toxic to animals. It is less toxic to the liver even when given together with alcohol, seldom producing any degree of liver necrosis. Furthermore, calcium deficiency has been shown not to increase the toxicity of tetrachlorethylene, and there seems to be no doubt that it is a safer drug clinically. However, it may be considerably less effective as a vermifuge. It is very difficult to secure good evidence on that point.

As for oil of chenopodium, the margin of safety is not very large. Minor toxic symptoms are frequent and some deaths have been reported. The majority of deaths have followed overdosage in the usual sense, doses larger than those recommended for therapy. Here are some interesting comparisons: In normal cats the oral minimum lethal dose is 0.4 cc. per kilogram (equivalent to 24 cc. total for a 60 Kg. man). In starved, malnourished cats the oral minimum lethal dose is 0.15 cc. per kilogram (equivalent to 9 cc. total for a 60 Kg. man). The maximum therapeutic dose is stated to be about 3 cc., and in debilitated and anemic patients, using these figures as a rough measure of comparison, the margin of safety, as you can see, would not be great. Now if olive oil is administered with oil of chenopodium to starved cats the oral minimum lethal dose becomes 0.3 cc. per kilogram; that is, the toxicity is reduced. It is possible that serious poisoning by chenopodium is not seen frequently in man because it is customary to follow it with castor oil.

DR. HARRY B. RICHARDSON: Does it have to be an unsaturated oil?

DR. TRAVELL: Mineral oil, which is a mixture of saturated hydrocarbons, does not influence the toxicity of any of these anthelmintics. The experimental work has been done in the main with unsaturated oils, chiefly olive oil. Castor oil and cottonseed oil have also been shown to reduce the toxicity of some phenol derivatives.

The toxic effects of hexylresorcinol are of minor importance in the use of this drug. I am sorry that we do not have time to consider them now and hope that this topic will be discussed later.

DR. GOLD: We are fortunate in having Dr. Mackie with us this morning to lead the clinical discussion.

DR. THOMAS T. MACKIE: Before discussing the details of therapy for these different parasites I think it may be of some value to refer to their clinical importance. Beginning with the cestodes *Taenia saginata* and *Diphyllobothrium latum*, for the most part the indications for therapy are esthetic rather than purely clinical and medical. *Taenia saginata* does not produce disease. It may produce chronic indigestion, but it does not live strictly speaking at the expense of the host, and certainly not at the expense of the host's tissues. The reverse, however, may be true with respect to *Taenia solium* or pork tapeworm because under certain conditions the human being may become the intermediate as well as the definitive host. If a ripe proglottis is carried back into the human stomach by reverse peristalsis, the contained ova are liberated. The viable embryo then immediately penetrates the mucous membrane and is carried by the blood stream to different parts of the body, where it forms the pathologic response which is

known as the cysticercus cellulosae. Fortunately, the pork tapeworm is exceedingly rare. Almost invariably the members of this genus that we see are *Taenia saginata*, but it is of some importance to know definitely in a specific instance which one we are dealing with, and there is a simple and easy method of identification with which many of you are probably familiar. That is simply taking one of the segments of the worm, placing it on a glass slide, placing another slide over it, pressing the two together, and holding it up to the light. The genital orifice is visible on the lateral margin, the vaginal portion of the genital tract extending into the body of the worm joined by the two stem branches of the uterus. If the main collateral branches of the uterus are in the order of thirty or more per segment, we know that we are dealing with the nonpathogenic *Taenia saginata*; if they are fifteen or twenty, we know that we are dealing with *Taenia solium*, the pork tapeworm, for which we have an emphatic indication for therapy.

Diphyllobothrium latum was believed many years ago to produce a characteristic anemia, and in fact in one stage of the early work on pernicious anemia it was suspected that it might be one of the factors in producing this type of blood dyscrasia. That impression, however, has been thoroughly exploded. By way of illustration it may be of some interest to cite the fact that certain investigators have deliberately infected themselves with *Diphyllobothrium latum*, which they carried in their intestinal tracts for many months. Repeated observations of their blood counts throughout this period revealed no evidence of anemia.

As to the question of therapy, the anthelmintic drug most commonly used in the past in the treatment of cestodes is of course the extract of male fern or filix mas, that is, the oleoresin of aspidium. Unfortunately this is not particularly effective, and one has very many failures. It is recommended that the individual be placed on a starvation diet for a period of approximately two days before treatment. I question the necessity for that. It is likewise recommended that the individual be given a strong saline purge on at least two occasions within that period of forty-eight hours. I think there is a good deal of question about the necessity for that procedure. Oleoresin of aspidium is recommended to be given on an empty stomach on the third day in doses of 2 cc. in capsules at half hourly intervals for three doses. Some men who have worked in this field recommend that following the final dose approximately 2 cc. of spirit of turpentine be given likewise by capsule. This in turn is followed by a saline purge and two hours later by a large soap suds enema to ensure complete evacuation of the colonic contents.

It is further recommended that if the head is not obtained by such treatment the procedure be repeated again in approximately two to three weeks' time.

Probably a very much more effective method of approach is the use of carbon tetrachloride. As was emphasized a few moments ago, whenever this drug is used definite precautions have to be taken. We have to be sure that the individual has an ample amount of calcium in his blood stream. It is apparent that most individuals living on customary diets are none too well supplied with this mineral. It is important that the patient be on a high carbohydrate, low fat and low meat diet for a period of at least two or three days prior to treatment. It is important that alcohol be completely withheld during the period prior to treatment. It is important that food be completely withheld for a matter

of four or five hours after the drug has been administered and until catharsis has occurred in response to magnesium sulfate.

The roundworms fall into a different group from the point of view of therapy just as they do with respect to their biologic characteristics. Hookworm and its effects on the human organism are so well known that it is not necessary to emphasize the clinical picture, with perhaps this single reservation: There is a good deal of question in my mind as to the desirability of subjecting people to the potential hazard which treatment of these parasites entails unless we have evidence that the hookworms are actually producing some definite harm to the individual. That harm is evidenced first by the appearance of anemia. That is the most common response; and if, as is frequently the case in this part of the world, we see individuals coming back from the South who on stool examination show a few ova of *Uncinaria* but who are free from symptoms of any type and who have a normal hemoglobin and red cell count, it does not seem to me desirable to subject them to therapy because after a greater or longer period of time outside the endemic area they automatically become freed of the parasites which they carry.

Infection by the roundworm *Ascaris* is a different story, because these are large worms which are capable of producing serious damage in the host, but unlike the hookworm they do it mechanically. They are not strict parasites in the sense that they do not live on the host's tissues, but an adult ascaris may migrate into the appendix, it may and occasionally does migrate into the common bile duct, it may and occasionally does migrate up through the stomach, up the esophagus, and into the paranasal sinuses. I have seen a patient remove a large ascaris from his nose. Furthermore, in young children heavily infected, *Ascaris* may form a mass in the small intestine which can give rise to intestinal obstruction.

Occasionally a patient may carry a few of these worms, yet stool examination yields no evidence whatever to confirm their presence. That is, of course, due to the fact that male worms may be present and the gravid or egg-laying females absent.

The pinworm again lives one might almost say in symbiosis with its host. It does not destroy the tissues of the host. It may cause definite appendicular colic, especially in young children when single worms or groups of them reach the depths of the appendix. As has been pointed out previously, the treatment of this infection is exceedingly difficult for several reasons. In the first place the life cycle is not fully known. One finds statements in the literature that the period from ingestion of the ovum to the development of the fully gravid female requires from two weeks to two months. There is also evidence by analogy that what is technically spoken of as hyperinfection occurs; in other words, that under certain conditions the gravid female may lay her ova within the intestinal tract of the infected individual, and these ova there develop into the succeeding generation. The effects which are produced by this parasite are primarily the result of the cutaneous irritation produced by the migrating females as they emerge from the anus. These effects are disturbance of sleep, local skin irritation and the associated nervous phenomena which may occur especially in children.

The whipworm can cause definite lesions in the human colon. It customarily burrows into the mucosa, and cases of actual dysentery resulting from whipworm infestation have been described. They are, however, exceedingly rare. In most instances the symptoms asso-

ciated with this infestation are so slight, and the hopes of effective therapy likewise so slight, that I do not feel that one is justified in attempting strenuous measures of therapy.

Again, we have a group of drugs which are applicable to the roundworms, that is to the nematodes, and which are not applicable to the cestodes. Carbon tetrachloride, already discussed, is an exception in that it is effective against both. In the past, oil of chenopodium was the drug of choice for the treatment of ascaris and hookworm infestations. It is given alone or in so-called mixed or combined treatments. The mixed treatment that is recommended is from 1 to 1.5 cc. of carbon tetrachloride for an adult, followed an hour later by 0.5 cc. of oil of chenopodium, and followed an hour later by an ounce of magnesium sulfate. The combined treatment consists of a single dose of small amounts of each of these two drugs, again followed shortly by a magnesium sulfate purge. Hexylresorcinol, however, is to be preferred to either.

The treatment of *Oxyuris*, the pinworm, is most unsatisfactory, and as has already been pointed out one of the most important factors is cleanliness. In the case of young children it may not only require careful cutting of the finger nails and scrupulous cleansing of the hands but it may mean even the wearing of gloves at night and the tying of the arms to the head of the bed so that the child cannot scratch. It requires the use of a mercurial ointment to the anal region at night, precautions concerning clothing and linen which may be contaminated, and repeated use of an effective anthelmintic drug. Recently, hexylresorcinol in doses of 1 Gm. for adults or from 0.6 to 0.8 Gm. for children has been reported to give very good results. This is given on an empty stomach and no food is permitted for five hours. Subsequently an enema of 0.1 per cent of an alkaline solution of hexylresorcinol is given and held for fifteen or twenty minutes. In practice, the oxyuris is by far the most difficult of all these infections to eradicate.

DISCUSSION

DR. GOLD: The conference is now open for general discussion. Dr. Smillie, would you care to make any comments?

DR. WILSON G. SMILLIE: The ideal anthelmintic is one that will remove all the parasites harbored without danger to the host at all. We have been looking for the ideal vermifuge for a long time, but it has never been discovered. I think we owe a great deal to Lamson, however, for his extensive pharmacologic studies on these vermifuges.

My recommendation is the use of hexylresorcinol. It will remove 90 per cent of *Ascaris* in a single administration without any danger to the host. It will remove from 75 to 85 per cent of the hookworms in a single administration. The great difficulty with oil of chenopodium is that its toxic dose is so close to its therapeutic dose. We treated over a million people in Brazil, in one country alone, with oil of chenopodium and had a very wide experience with its toxicity. We had some twenty-two deaths. Four persons to whom I had administered the drug died. Once you have seen a person die of oil of chenopodium poisoning you hesitate ever to give it again. It is a terrible death. The drug is one that has a special affinity for the central nervous system. Once the convulsions begin, lasting from twenty-four to thirty-six or forty-eight hours, while you must sit by and see the child finally die, is an awful experience. Carbon tetrachloride may also be quite

toxic. It is a very effective drug it is true, but it is dangerous. Some one mentioned the very first case of intoxication, which was described on a plantation in Brazil. That man recovered. I have had two deaths, however, from the drug, and here again it is a devastating experience, as you can well imagine, so that I do not recommend either oil of chenopodium or carbon tetrachloride. Tetrachlorethylene is as effective as carbon tetrachloride. Lambert in the South Sea Islands has now treated some 20,000 to 40,000 persons, and he has had no deaths as yet. His studies indicate that the drug is exceedingly effective. Hexylresorcinol has one great disadvantage, and that is it is expensive. Therefore it is quite impossible to use this drug on a wide scale among the poor people that are infected. It is a very serious matter of course, but nothing can be done about it. I should say then that hexylresorcinol, given in a single gram dose early in the morning on an empty stomach, followed within an hour to an hour and a half by a saline purge, with no food taken until noon, is by far the most satisfactory method of anthelmintic therapy we have at the present time. Tetrachlorethylene is given in 3 cc. doses on an empty stomach, in the early morning following a light supper. No breakfast is eaten. The drug is given at 7 o'clock in the morning; 1.5 cc. is taken in hard gelatin capsules, followed an hour later by another 1.5 cc. and followed an hour later by a purge of magnesium sulfate. The results are splendid.

Some one mentioned the reduction in toxicity of oil of chenopodium when given with oils. The quickest way to kill a dog is to give him a mixture of a little oil of chenopodium with bile. If you mix the drug with castor oil, however, it is relatively safe, and so if you must give oil of chenopodium I would recommend that you administer, to a child with *Ascaris*, 0.5 cc. with a tablespoonful of castor oil. Mix the two together, and you will get excellent results with little danger of intoxication.

The worm that can be most easily removed is *Ascaris*. The next is the hookworm. The pinworms, as has been said, are difficult to remove. The whipworms, because they thread themselves through the mucous membrane, are very hard to remove. Actually, as Dr. Mackie says, it is not necessary often to get them.

DR. GOLD: Is there any other discussion?

DR. MCKEEN CATTELL: Have there been no untoward effects found to follow the use of hexylresorcinol?

DR. SMILLIE: Yes, in children that chew up the capsules. They get a burning sensation of the mouth. It is very disagreeable, so the drug is put up in an iron-bound capsule which the child will find impossible to chew. Once it gets into the stomach there may be a slight burning sensation, but no serious toxic results follow.

DR. TRAVELL: Dr. Lamson has published a study on dogs in which he examined the gastrointestinal tracts after giving hexylresorcinol to see what happens in the stomach when the capsule is not chewed up. He reported submucous hemorrhages and also superficial ulceration of the gastric mucosa; but he found that the ulcerations were transient and had practically healed within seventy-two hours, leaving no permanent lesions. He also carried out a study on a large series of alkylphenols to try to find one that would be less irritant than hexylresorcinol and he came to the conclusion, using the pig *ascaris* as a test object, that the ascaricidal action could not be divorced from the irritant action and that any procedure, such as the giving of oil,

which tended to reduce the irritant action of hexylresorcinol also greatly reduced its effect on the parasites.

DR. MACKIE: I have used the drug in Guatemala in much larger than the recommended dosage without any evidence of toxic symptoms other than the complaint of some epigastric burning for an hour or an hour and a half after administration.

DR. GOLD: This is hexylresorcinol?

DR. MACKIE: Yes.

STUDENT: Is hexylresorcinol good for flatworms?

DR. SMILLIE: No, not very effective for flatworms.

VISITOR: Would a question in differential diagnosis be out of order here? I should like to know what Dr. Mackie thinks regarding the skin test material which I believe is put out by Lederle to differentiate between these two types of worms, particularly when repeated stool examinations have failed to identify the parasite.

DR. MACKIE: It is not a very dependable or a very worth while method of diagnosis. I do not think it is particularly practical.

DR. SMILLIE: If you cannot find the ova in the stools it does not make any difference anyway, for the infection is so light that it is not of practical importance. There is one point that ought to be emphasized in therapy, and that is clearly brought out in the studies of Rhoads and Castle in Puerto Rico. After you remove hookworms in a heavily infested person the child will not get well unless you give him large amounts of iron. Give it to him in large doses in the forms in which it is readily available. In their Puerto Rico experiments they were willing to recommend, if they had to make a choice between iron and the anthelmintic, to give the iron and forego the anthelmintic. The child builds up hemoglobin rapidly even though the worms are continually taking the blood. The sensible thing to do is to get rid of these worms and then give the patients large doses of iron; but the customary method of giving the anthelmintic and then expecting the child to get well is not good therapy, because they must have large amounts of readily available iron to secure prompt recovery.

DR. GOLD: Is there a toxin liberated by the hookworm?

DR. SMILLIE: No, it was thought for many years that the hookworm produced a toxin, but all of Castle-Rhoads' studies show the anemia is due purely to loss of blood. Wells, working with the dog, in studies in which he opened the intestine of the dog and watched the living worm in gross, found that this worm not only sucked blood for digestion but that there was also a continued stream of blood flowing through the worm.

DR. JOHN E. DEITRICK: Is there anything new in the management of trichinosis? We still see that in New York, probably more commonly than any of these other worms.

DR. TRAVELL: Better control of the kind of garbage that is fed to pigs.

DR. MACKIE: Better control of cocktail canapés.

DR. DEITRICK: There seems to be little we can do for these patients.

DR. SMILLIE: Some recommend giving an anthelmintic, but the results are rather doubtful because by the time you see the patient the damage is done and you cannot reach the worms. Any vermifuge that has ever been discovered that can be used to kill the worm in the general circulation is toxic to the host. Lambert tried that. He used three cannibals that were convicted

to be shot. He gave one oil of chenopodium intravenously with disastrous results. He gave intravenous vermifuges to the others as well, but even small doses in the circulation are toxic.

DR. DEITRICK: Is it true that the adult trichinae will persist in the intestinal tract for two or three or four weeks?

DR. SMILLIE: Yes, but they are not within the intestinal tract. They are buried deeply in the mucosa.

DR. DEITRICK: When a patient with trichinosis is admitted, we give him a large dose of magnesium sulfate and attempt to clean out as many of the worms as possible. That is practically all we can do.

DR. SMILLIE: It is perfectly reasonable therapy. I would also suggest that tetrachlorethylene be given because you cannot do the patient any harm and you may get some of the adult worms.

DR. GOLD: Am I correct in assuming that both Dr. Smillie and Dr. Mackie prefer hexylresorcinol to oil of chenopodium for the treatment of roundworms?

DR. MACKIE: Yes. I think it is much the safest.

DR. SMILLIE: For effectiveness, oil of chenopodium is in a class by itself. A dose of 1.5 cc. is perfect. One can remove from 90 to 95 per cent of the worms in a single dose, but it is dangerous. That is the trouble.

DR. GOLD: If there are no further questions, we will adjourn.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

CEVITAMIC ACID-LEDERLE (Ascorbic Acid-Lederle) (See New and Nonofficial Remedies, 1939, p. 500).

The following dosage form has been accepted:

Tablets Ascorbic Acid-Lederle, 0.025 Gm.

SALYRGAN-THEOPHYLLINE SOLUTION.—Mersaly-Theophylline Solution.—A solution containing 10 per cent by weight of sodium [o(hydroxy-mercuric-methoxy-propyl-carbamyl) phenoxy] acetate and 5 per cent by weight of theophylline.

Actions and Uses.—Salyrgan-Theophylline Solution has been demonstrated to produce less local reaction on intramuscular injection than salyrgan alone and to be somewhat more effective. It is believed that the more rapid resorption of salyrgan in combination with theophylline accelerates diuresis and, by preventing the deposition of mercury, improves the local tolerance. Salyrgan-theophylline solution is proposed as a diuretic for dropsy in cardiorenal disease and in nephrosis, ascites of liver diseases and other conditions. It is contraindicated in acute nephritis and chronic kidney disease in an advanced stage with marked tubular and glomerular changes; also intestinal inflammation with diarrhea. As do other mercurials, salyrgan-theophylline solution may give rise to side effects, particularly stomatitis, gastric disturbance, more or less diarrhea, vertigo, headache, febrile reaction and cutaneous eruptions. When the use of salyrgan-theophylline is continued over a prolonged period of time the urine should be examined from time to time for albumin, casts and blood cells.

Dosage.—For Adults: For susceptibility test of patient the first dose should be 0.5 cc. If well tolerated, the dose may be increased to 1 cc. on the following day. In some cases 2 cc. may later be required for the full effect. Usually injections are not given more frequently than every three or four days. After relief of the dropsy, recurrences can often be prevented by occasional injections. For Children: The dose for children

of salyrgan-theophylline is proportionately less than that for adults (0.25 cc. to test susceptibility, followed by 0.5 or 1 cc. the following day).

Manufactured by Winthrop Chemical Company, Inc., New York. "Salyrgan" U. S. patent 1,693,432 (Nov. 27, 1928; expires 1945). U. S. trademark 188,515.

Ampoule Solution Salyrgan-Theophylline, 1 cc.: Each cubic centimeter contains salyrgan 0.1 Gm. and theophylline 0.05 Gm.

Ampoule Solution Salyrgan-Theophylline, 2 cc.: Each cubic centimeter contains salyrgan 0.1 Gm. and theophylline 0.05 Gm.

Salyrgan-theophylline solution is an aqueous, colorless, odorless, bitter solution, of slightly alkaline reaction. The pH of the solution is approximately 7.8 (± 0.2). To differentiate from salyrgan solution, add 0.5 cc. of acetic acid to 5 cc. of salyrgan-theophylline solution: no immediate precipitation takes place. Add 3 cc. of formic acid to 5 cc. of salyrgan-theophylline solution: a white precipitate is formed which, on boiling, dissolves, leaving a gray residue of metallic mercury. Add 10 cc. of distilled water and 10 cc. of diluted hydrochloric acid to 3 cc. of salyrgan-theophylline solution; boil for ten minutes and cool; extract the resulting salicyl allyl amido acetic acid with 20 cc. portions of ether; evaporate off the ether and dry the residue over phosphorus pentoxide in a vacuum desiccator; the melting point of the residue (salicyl allyl amido acetic acid) is from 120 to 121 C. Through the aqueous phase from which the salicyl allyl amido acetic acid has been extracted, bubble sufficient hydrogen sulfide gas to precipitate all mercury; filter and evaporate the filtrate to 20 cc.; after cooling, add 10 Gm. of sodium acetate; extract the solution in a small liquid-liquid extractor with 30 cc. of chloroform; evaporate off the chloroform and dry the residue (theophylline) in a desiccator of sulfuric acid; the melting point of the residue is from 269 to 272 C. The residue gives the murexide reaction (U. S. P. XI, page 384). Add 1 cc. of silver nitrate test solution to 1 cc. of salyrgan-theophylline solution: a white precipitate of silver-theophylline results which does not go into solution on addition of 2 cc. of diluted ammonium hydroxide solution. Add 0.5 cc. of diluted acetic acid (1:1) and 0.3 cc. of sodium sulfide water to 5 cc. of salyrgan-theophylline solution: only a very faint coloration of the solution is noticeable.

ASSAY FOR SALYRGAN: To 5 cc. of salyrgan-theophylline solution in a 250 cc. beaker add slowly 10 cc. of sulfuric acid. Warm on a steam bath and add cautiously at five minute intervals four 0.5 cc. portions and one 2 cc. portion of a 30 per cent hydrogen peroxide solution. Heat for at least one hour after the last addition of hydrogen peroxide: the solution is colorless. Add 50 cc. of water and potassium permanganate solution in slight excess. Decolorize with oxalic acid solution. Add 10 cc. of concentrated sulfuric acid, 2 cc. of ferric ammonium sulfate T. S., and make up the total volume to 100 cc. with water.

Prepare a control. To 78 cc. of water add 20 cc. of sulfuric acid, 2 cc. of ferric ammonium sulfate and 0.05 cc. of N/10 potassium thiocyanate solution. Titrate the diluted salyrgan-theophylline solution with N/10 potassium thiocyanate solution to the same intensity of color: each cubic centimeter of N/10 potassium thiocyanate solution used is equivalent to 0.02528 Gm. of salyrgan; the amount of salyrgan corresponds to not less than 9.5 per cent nor more than 10.5 per cent.

ASSAY FOR THEOPHYLLINE: To 5 cc. of salyrgan-theophylline solution in a 200 cc. Erlenmeyer flask add 1 cc. of sulfuric acid and 50 cc. of water. Bubble hydrogen sulfide gas through the solution until the mercury is precipitated in the form of mercury sulfide. Remove the excess hydrogen sulfide by boiling and filter while still warm. To the filtrate and washings in a 200 cc. Erlenmeyer flask add 5 Gm. of ammonium acetate and 20 cc. of N/10 silver nitrate solution. Evaporate until the volume has been reduced to 50 cc. Filter with vacuum while still warm. Wash the resulting cake with three 10 cc. portions of water. Add 5 cc. of nitric acid to the washings and filtrate. Add 2 cc. of ferric ammonium sulfate T. S. and cool. After cooling, titrate the excess silver with N/10 potassium thiocyanate: each cubic centimeter of N/10 silver nitrate indicates the presence of 0.0198 Gm. of theophylline; the amount of theophylline corresponds to not less than 4.75 per cent nor more than 5.25 per cent.

ESTRONE (THEELIN) (See New and Nonofficial Remedies, 1939, p. 345).

Estrone-Lilly.—A brand of estrone (theelin)—N. N. R.

Manufactured by Eli Lilly & Co., Indianapolis, by license from St. Louis University under U. S. patents 1,967,350 and 1,967,351 (July 24, 1934; expire 1951). No U. S. trademark.

Ampoules Estrone, 0.1 mg. in oil, 1 cc.: Each cubic centimeter contains estrone 0.1 mg. (1,000 international units) in a bland vegetable oil.

Ampoules Estrone, 0.2 mg. in oil, 1 cc.: Each cubic centimeter contains estrone 0.2 mg. (2,000 international units) in a bland vegetable oil.

Ampoules Estrone, 0.5 mg. in oil, 1 cc.: Each cubic centimeter contains estrone 0.5 mg. (5,000 international units) in a bland vegetable oil.

Ampoules Estrone, 1.0 mg. in oil, 1 cc.: Each cubic centimeter contains estrone 1.0 mg. (10,000 international units) in a bland vegetable oil.

Vaginal Suppositories Estrone, 0.2 mg.: Each suppository contains estrone 0.2 mg. (2,000 international units) in a glycerin base.

ESTRIOL (THEEOL) (See New and Nonofficial Remedies, 1939, p. 347).

Estriol-Lilly.—A brand of estriol (theeol)—N. N. R.

Manufactured by Eli Lilly & Co., Indianapolis, by license from St. Louis University under U. S. patents 1,967,350 and 1,967,351 (July 24, 1934; expire 1951). No U. S. trademark.

Pulvules Estriol, 0.06 mg.: Each pulvule contains estriol 0.06 mg.

Pulvules Estriol, 0.12 mg.: Each pulvule contains estriol 0.12 mg.

Pulvules Estriol, 0.24 mg.: Each pulvule contains estriol 0.24 mg.

RIBOFLAVIN (See New and Nonofficial Remedies, 1938, p. 479).

Riboflavin-Merck.—A brand of riboflavin—N. N. R.

Manufactured by Merck & Co., Inc., Rahway, N. J. No U. S. patent or trademark.

Ampule Riboflavin-Merck, 10 mg.

Ampule Riboflavin-Merck, 100 mg.

Riboflavin-Merck, 1 Gm. Bottle

SATURDAY, JULY 29, 1939

TUBERCULOUS TRACHEOBRONCHITIS

Eppinger¹ in 1881 gave the first complete anatomic description of tuberculous tracheal ulceration, pointing out the tendency of the ulcers to localize in the lower part of the trachea. In about one eighth of his necropsies the lesions were not associated with tuberculous laryngitis. He believed they were an extension from the adjacent tuberculous lung tissue and caseating peribronchial lymph nodes. Despite this excellent description, tracheobronchitis as a complication of pulmonary tuberculosis received but scant attention in the succeeding decades. With the revival of interest in tracheobronchial tuberculous disease, a number of studies of necropsy material have become available. Reichle and Frost,² on the basis of microscopic examination of the tracheobronchial tree in thirty-seven cases in which death occurred from chronic phthisis, concluded that the common modes of infection of the major bronchi are by contiguity from the diseased lymphatics and lymph nodes of the peribronchial tissue or by continuity occurring secondarily to an implantation tuberculosis in the lower lobe and in the bronchi draining a tuberculous cavity. They considered implantation the least important mechanism of invasion of the tracheobronchial mucosa, particularly in the case of the larger bronchi because of the protective influence of the cilia, mucus and bronchial peristalsis. Bugher, Littig and Culp³ studied 122 cases of pulmonary tuberculosis at necropsy. In their experience, extension from peribronchial tissue was not an important mechanism. They state that in no instance of tracheotuberculosis did they find diffuse peritracheal tuberculosis and that lesions of the tracheal mucosa occurred without tubercles being found in the adjacent peritracheal lymph nodes. They conclude that extension from the peritracheal tissue did not assume an important role. They were impressed with the tendency of the lesions to occur with great frequency on

the posterior wall in patients who had been recumbent for long periods. The fact that the sputum was rich in tubercle bacilli in all these cases further emphasized the probable role of implantation. While laryngeal tuberculosis was frequently concurrent with tracheobronchial tuberculosis (76 per cent of their cases), it was considered by them as not causally related.

Recent advances in roentgenology and bronchoscopy together with a renewed interest on the part of the phthisiatrists have led to clinical recognition of tuberculous tracheobronchitis. Its presence is to be suspected when a patient exhibits a persistent wheeze and rattling, asthmatoïd attacks, erratic rises in temperature not associated with extension of the pulmonary disease, paroxysms of violent coughing, dyspnea and cyanosis on slight exertion, excessive amount of a tenacious sputum rich in tubercle bacilli, and a great variation in its amount from day to day. Roentgenograms are likely to reveal lobar or total pulmonary atelectasis with or without collapse therapy. Total pulmonary atelectasis taking place rather abruptly after induction of a pneumothorax is suggestive. Roentgenograms may further demonstrate an unexpected spread of a tuberculous infiltration or a rapid enlargement of a cavity.

The recent contributions of Clerf, Tucker, Myerson, Samson and others have demonstrated the relative innocuousness of bronchoscopy in pulmonary tuberculosis, as well as its value in the recognition and to some extent in the treatment of tuberculous tracheobronchitis and its complications. Diagnostic bronchoscopy is, however, contraindicated in the presence of hemoptysis, severe laryngeal ulceration or hopeless pulmonary disease. McIndoe and his co-workers⁴ concluded, after an experience of two years during which 272 patients were examined, that routine bronchoscopic examination is not necessary for the discovery of significant tuberculous tracheal and bronchial lesions. Bronchoscopy in their opinion should be performed only when suggestive signs or symptoms are present. Bronchoscopy did not have a deleterious effect on any patient in their group.

Tuberculous tracheobronchitis definitely aggravates the pulmonary disease. Climatic treatment, ultraviolet rays, tuberculin therapy and roentgen therapy have not thus far contributed much to the amelioration of this condition. Major collapse therapy is rather to be avoided in cases complicated by tracheobronchial ulceration, since it may further add to the already existing difficulty in raising the sputum and to the respiratory embarrassment. According to Samson,⁵ symptomatic improvement has followed in select cases the bronchoscopic aspiration of retained secretions, chemical shrinkage of edematous mucosa or the cautious dilation of circumscribed bronchial stenoses.

VITAMIN K

Clinically active vitamin K has been obtained principally from putrefied fish meal and alfalfa meal. In 1933 Anderson and Newman¹ isolated a pigment from human tubercle bacilli which they designated phthiocol and the chemical constitution of which was determined as 2-methyl-3-hydroxy-1,4-naphthoquinone. The synthetic preparation of this quinone was tested by Almquist and Klose,² who found that it possessed antihemorrhagic activity similar to that of vitamin K. The term phthiocol however has not been adopted generally by all other American or foreign investigators of this field or by the Council on Pharmacy and Chemistry. The preparation and purification of crystalline concentrates have proceeded rapidly and purified products have been announced almost simultaneously in many different laboratories. From Europe in March of this year a report appeared by Dam, Karrer and their colleagues³ on the isolation of vitamin K from alfalfa. There seems to be now general agreement that the vitamin contains a quinone structure. Thus Almquist and Klose declare that the antihemorrhagic activity of phthiocol lies between that of the methyl naphthoquinone and the hydroxy naphthoquinone. Ansbacher and Fernholz⁴ found, in confirmation, that 2-methyl-1,4-naphthoquinone is practically as active as vitamin K.

Fieser and his colleagues,⁵ from experiments with various quinones on day-old chicks, suggest that some of the 2-hydroxy-3-alkyl-1,4-naphthoquinones possess positive vitamin K activity. In spectographic data reported also by Fieser and his co-workers⁶ there is close correspondence indicated between the natural vitamins and model substances of the postulated structure of 2,3-dialkyl-1,4-naphthoquinones.

Similarly the most recent work of MacCorquodale, Binkley, Thayer and Doisy⁷ led them to the belief that the structure of the vitamin K₁ molecule is 2-ethyl-3-phytyl-1,4-naphthoquinone. Obviously this work of chemical identification has advanced to the point at which one can be reasonably certain that at least much of the activity of what is now considered due to vitamin K can be attributed to one or more quinone derivatives. It seems by no means certain as yet, however, that the various substances crystallized and identified are identical in action, although it can be confidently anticipated that this question will soon be resolved.

MUCH OF THE recently acquired clinical information on vitamin K is adequately summarized elsewhere in this issue in the articles by Smith and his associates⁸ and by Butt and his associates.⁹ Conclusions cannot now be drawn as to the relative clinical activity of the more purified products so recently discovered. Furthermore, the naming of the final purified active crystalline product which will represent the efforts of such a large group of investigators must be carefully considered in order to conform to the best principles of scientific terminology and the avoidance of any therapeutically suggestive designation.

CELLULAR RESPIRATION

Lavoisier's conception of respiration was the combustion of foodstuffs through oxygen. Although foodstuffs are oxidized by the body cells at relatively low temperatures, they do not react readily with oxygen in the laboratory. Powerful oxidizing agents are required to duplicate the combustion which occurs so readily in the organism. In view of this difference, the mechanism of cellular oxidation has long puzzled investigators. Work on this problem has been discussed in recent reports by Barron¹ and by Szent-Györgyi.² There are several ways in which the oxidation of a substance may be effected; addition of oxygen or removal of hydrogen accompanied by withdrawal of electrons, or simply removal of electrons without addition of oxygen or removal of hydrogen, results in oxidation. The cell is capable of oxidizing metabolites with the help of catalytic systems, oxidation being accomplished by means of a series of oxidation-reduction reactions involving a variety of substances in the tissues.

Since oxygen does not readily attack molecules of absorbed food materials at the comparatively low temperature of the body, the process must be activated in some way in order to proceed at this temperature. One of the first links in a chain of such reactions was described by Warburg, who discovered an enzyme capable of activating molecular oxygen. Another important contribution was made by Keilin, who showed that certain pigments present in cells and called "cytochromes" are involved in cellular respiration. Three cytochromes have been described, and there is an iron atom in at least one, and probably in all of them. This metal atom is the active constituent of the molecule; in respiration it is susceptible of being alternately oxidized and reduced. A cytochrome, prepared in pure form, was not oxidized by atmospheric oxygen at a measurable rate. Important from the aspect of cellular respiration, however, is the fact that oxidation may be effected by an oxidase which is either identical with

Warburg's respiratory enzyme or similar to it. In the cell also are enzymes called dehydrogenases. These act on metabolites in such a way that certain hydrogen atoms become labile and amenable to being readily removed by a suitable acceptor (oxidizing agent). Consequently a typical oxidation-reduction reaction may take place, the metabolite being oxidized and another substance being reduced. The reduced material may then in turn be oxidized by still another substance. Thus there is a chain of electron transfers in which hydrogen of the foodstuff serves as an electron donator, substances such as the cytochromes act as electron transmitters, and oxygen behaves as the ultimate electron acceptor. Cellular respiration is therefore simply the process by which the cell extracts energy from the molecules of food materials, the release of energy depending on the foregoing series of reactions. Szent-Györgyi has emphasized the role that may be assumed by such simple metabolites as fumaric and succinic acids as intermediary carriers in cellular respiration. Oxidation-reduction systems involving phosphoriboflavin-protein and diphosphorpyridine-nucleotide have also received attention and are of considerable importance in biologic oxidation processes.

Cellular oxidation is conceived as occurring in stages, the system of more negative potential being oxidized by the reduction of the system of more positive potential in a series of graded steps up to the reduction of molecular oxygen. Like locks in a canal, as Barron describes it, these reversible systems gradually release the oxidation energy. Oxygen as the ultimate hydrogen acceptor in cellular oxidation is reduced to form water, one of the end products of cellular respiration. In which step of the oxidation-reduction series the other end product, carbon dioxide, appears is scarcely known. Some of it may arise through intermolecular oxidation-reductions of ketonic acids, some by the interaction of α -ketonic acids and amino acids, some by the oxidation of pyruvic acid and other similar processes.

A recent addition to our knowledge in the field of cellular respiration is the observation that certain vitamins have an important part in processes of biologic oxidation. Riboflavin, for instance, is known to form an integral part of an oxidation-reduction system and presumably is a dietary essential because it is required by the body for the formation of this system. Likewise diphosphothiamin is known to be involved in a system effecting the oxidation of pyruvic acid, and nicotinic acid amide has been found to be a structural unit of a coferment which is thought to play a part in oxidation-reduction reactions in the cell. The therapeutic properties of nicotinic acid in cases of pellagra are due, according to Spies, at least in part, to its effect on codehydrogenase.³

Much of our knowledge of possible mechanisms of cellular respiration has been obtained as the result of a study of isolated enzyme systems. Strictly speaking,

the results hold only for the conditions for which they have been worked out. These studies have, however, given an insight into the mechanisms involved in cellular oxidation and afford information concerning the role of some vitamins as essential components of enzymes involved in fundamental biologic reactions.

Current Comment

WHAT IS OSTEOPATHY?

In the State Board issue of *THE JOURNAL* the question What is Osteopathy? was asked.¹ One answer is found on page 447 of this issue. Osteopathy is a system of therapy without benefit of operative surgery or the use of drugs as remedial aids. In Kansas the osteopaths procured the enactment in 1913 of legislation that authorized adherents of the cult to practice osteopathy as taught and practiced in legally incorporated colleges of osteopathy of good repute. Proponents of the legislation evidently thought that they had thus found an easy way to obtain the unlimited right to practice medicine without qualifying themselves as legitimate practitioners of medicine must do. All that was necessary, they apparently thought, was for osteopathic schools to add a bit of *materia medica* and operative surgery to their courses and thenceforth osteopaths would be entitled to practice medicine and surgery. Quite a simple procedure! Only it did not work! The Kansas court in the case abstracted in this issue emphasized the fact that a law is to be construed as of the time of its enactment. The use of drugs as remedial aids and the use of operative surgery, the court pointed out, formed no part of the practice of osteopathy in 1913 when the act was passed. The fact that schools of osteopathy may have since introduced instruction in those branches of medicine does not enlarge the scope of osteopathic practice. Osteopaths in Kansas, therefore, have no right to employ such agencies. That the court correctly interpreted the legislative intent in passing the osteopathic act is evidenced by the fact that the recent Kansas legislature, subsequent to the decision of the court, denied the importunities of osteopaths for legislation granting them extensive privileges in the field of medicine, the legislature being unconvinced that osteopaths were qualified to practice operative surgery with instruments and to use drugs. In several other states, including Georgia, Missouri, Nebraska, New Mexico and North Carolina, osteopaths have obtained the enactment of legislation containing phraseology similar to that used in the Kansas law. The Kansas decision is commended to the careful consideration of those states. The decision is of importance too in those states in which osteopathic laws do not specifically define what constitutes osteopathy, such as Arizona, Delaware, Idaho and Mississippi. The Supreme Court of Kansas has rendered a distinguished service to the people of the state in thus thwarting the efforts of a group of substandard healers to edge into the field of the practice of medicine through the back door.

MANUFACTURERS' POINT OF VIEW ON MEDICAL PATENTS IN RELATION TO PUBLIC WELFARE

A. W. LESCOHIER, M.D.
President, Parke, Davis & Co.
DETROIT

While listed on the program as presenting the manufacturers' point of view on medical patents in relation to public welfare, I wish to make it clear at the start that I am not undertaking to speak for the pharmaceutical industry. The majority of manufacturers might or might not agree with my views as expressed, which are purely personal but naturally based on such experience as I have had in the industry.

I presume that the motive underlying the calling of this conference has to do less with the advantages or disadvantages of our patent system than it does with the policy which should be encouraged, particularly in medical schools, with regard to their securing and owning patents and their administration when secured and owned.

However, one can hardly divorce these specific questions from the general philosophy of the patent system.

The general aspects of the patent situation and the relation of patents to social and economic progress have been discussed so often and so well as to require little additional comment.

Aside from the interesting discussions that have taken place today, I have no doubt that most of you either heard or subsequently read the presentations of Dr. Fishbein, Mr. Schley, Dean Russell and others in the symposium held under the auspices of the American Chemical Society at Rochester in September 1937. These various men reviewed most admirably the questions involved and there is little to be said to a group of this kind which is either new or novel. My discussion must necessarily be little more than an expression of agreement with some of the thoughts (not all of them) that have been repeatedly expressed by others.

Before taking up the relationship of patents to the public welfare, I should like to digress long enough to consider briefly the question of equity of the inventor. This is a subject perhaps less interesting to those associated with medical schools and other medical organizations than it is to industry. To one, however, who believes in the enterprise principle as applied to American life, it does not seem unreasonable to hold to the principle that the inventor (whether it be a firm that has spent years in research on a certain project and large sums of its stockholders' money or whether it be an individual who has given perhaps the best years of his life to the pursuit of some particular problem) should not go unrewarded when these efforts result in practical achievement. To deny this seems to me to deny the soundness of vital factors in the character and accomplishments of the American people. To refuse to any branch of industry—and this I contend applies to the pharmaceutical as well as any other—the opportunity to improve its business position by capitalizing the discoveries that it has made, or assisted to be made, would represent a departure from the principles which have had a large share in the progress of our business institutions and which have had important resultant effects on the progress of the nation.

There are some who may not agree as to the general advantages of the patent system but who in any event oppose the taking of patents on discoveries which fall within the field of medicine. Again, this is a subject which has been repeatedly and ably discussed. However, it is so fundamental that I wish to comment briefly on certain phases of it.

The chief objection which is offered to medical patents is not dissimilar to that advanced against the patent system gener-

ally, namely that patents lead to monopoly. It is argued that monopoly as a result of patent control is particularly undesirable in the case of medical preparations.

Monopoly as a result of patent ownership is an obvious possibility in medical just as well as with other patents. In considering this matter as related to medical products, however, it is well to examine the matter historically and see whether or not monopoly has been a matter of great practical significance. I think that an unbiased review of the facts will reveal that monopoly for the most part has been a theoretical rather than a practical consideration.

Only occasionally is a patent sufficiently broad in scope to cover any therapeutic field. Examples of such broad patents are the insulin patent and the scarlet fever patent, the administration of which has been reviewed by previous speakers. Neither of these patents, of course, was administered on a monopolistic basis. Usually patents on pharmaceutical or biologic products cover only a segment of the field and do not open up the possibility of eliminating competition. To illustrate, there are probably a dozen patents covering antianemic preparations but, nevertheless, it is a highly competitive market. There are many patents on mercurial antiseptics, bismuth compounds, arsenicals and vitamin preparations. Still these fields are all very actively competitive. For most patented products there are equivalents or sufficiently near equivalents to put the products in active competition. A manufacturer may enjoy a temporary advantage but it is usually not long before one or more of his competitors bobs up with a product which will serve the same purpose. Those of you who are engaged in the practice of medicine have but to review the patented products that you are using for this to be apparent. Those who represent pharmaceutical houses and have had experience in introducing new pharmaceutical products I am sure do not need to be convinced on this point.

I have previously referred to the protection of the equity of the inventor assured by our patent system. However, we all recognize that the chief objective of a patent system is not the rewarding of inventors or their sponsors. The object sought is the promotion of discoveries and inventions which will contribute to the public welfare. If this were not so, I have no doubt that patents would long since have become extinct for the reason that even in our democratic country society is much less interested in rewarding individual effort than it is in improving the common welfare.

In expressing the conviction that it has been a very important factor in the progress of the science of medicine, I do not advance the theory that the patent system is a *sine qua non* to research progress in medicine. We all know that many great discoveries have come from institutions and individuals with no patent interest whatever. The spirit of investigation is a part of the very warp and fabric of medicine.

Nevertheless, the patent system has been a driving force toward invention. Not particularly so with regard to medical men, but with others—especially chemists—whose activities are importantly related to the science of medicine.

We cannot ignore entirely human instincts or assume that the research worker, because he has an unselfish desire to contribute knowledge and service to humanity, must consider that he should therefore be improvident in his attitude toward his own future and the future of his family. I think it is fortunate not only for the chemist but also for society that he has not been shackled with inhibitions about patents because I am sure that otherwise many important discoveries would have been lost to mankind.

Aside from this fundamental matter of incentive, there is another important consideration which enters into this general picture, and that is the free disclosure of scientific work which

is encouraged by patents. There are probably few practical achievements in science which are purely individual. Most of the important accomplishments are made possible by knowledge developed by prior workers. It is true that the man who carries out the final step often reaps a reward out of proportion to the part he has played in the whole development. Nevertheless, the public welfare is served by the fact that a practical achievement has been reached. The far greater element of secrecy which would exist in the absence of a patent system would unquestionably be a great deterrent to scientific progress.

The patent system also fosters the development of research institutions affiliated with or supported by commercial laboratories. The activity of such research divisions is a consequential factor not only in regard to direct contributions but in cooperating with research laboratories in universities and elsewhere. Furthermore, such research departments are important in the transition of discoveries from their original state to that of practical utilization. There is the further fact that the existence of research laboratories affiliated with pharmaceutical and biologic manufacturing plants has had a very definite influence in raising the standards for manufacturing pharmacy and the promotion of constantly more rigid methods of standardization.

It would, of course, be ridiculous to assume that the research departments associated with such companies would languish and die in the absence of a patent system. Patents or no patents, such research would go on. There is, however, no gainsaying the fact that in the absence of some method of protecting the fruits of research we should not have had the same development in the past as has taken place; neither would there be the same motivation for continuing expansion.

The policy of pharmaceutical manufacturers is generally and definitely to protect their discoveries by patents. The majority of universities and colleges, on the other hand, to a large extent lack any definite policy. Some of them are vigorously opposed to patents on discoveries by members of their faculties of medicine. They regard taking patents as a step down from the ideals and traditions of medicine.

This state of mind is perhaps a natural result of that ingrained sense of service to humanity which distinguishes the profession of medicine. There is a deep-seated feeling that those high ethical standards which have glorified the doctor for countless generations must not be compromised.

One cannot do other than admire this stalwart adherence to ideals and hope that the principles which have maintained the medical profession on its high plane of service to humanity will always endure.

One can, however, disagree with the conclusion that aloofness on the part of medical institutions in the matter of patents is the only way, or even the best way, of accomplishing the greatest service to humanity in the matter of important discoveries. If we approach the subject realistically and not sentimentally, I think we shall find ample support for the conclusion that patents secured by medical schools may be so administered, and are being so administered, as not only to avoid conflict in the slightest degree with the ideals and traditions of medicine but, on the other hand, to be a strong constructive influence in their support.

It is of course obvious, to begin with, that patents controlled by universities and licensed to manufacturers often provide, through royalty, substantial sums of money for the promotion of new research. If this were the only consideration, however, it would not be difficult to understand why certain universities and colleges would not be interested in patents. Deriving additional revenue, even for research purposes, does not always loom up as a sufficiently important consideration for them to depart from time-tried policies.

This is not, however, the most important consideration: failure on the part of the university to take a patent may result in patent control passing into the hands of others who would not administer it with the same broad interest that would be exercised by the university. It by no means follows that the research worker, in publishing his work, gives his discovery to the world even though that is his intention. Omissions which he may easily make (not being patent minded) have the result that his publication is not a barrier to some one else securing a patent on some important phase which may dominate the situation. After

the unselfish American scientist has done the fundamental work, mass attacks on vital processes, organized in some instances not only on a national but even an international scale, may transfer the control from the American discoverer to such interests.

Another important consideration in university patents is the matter of product control. In the case of universities who own patents which they administer by license to pharmaceutical manufacturers they usually exercise a considerable degree of control over the potency and other quality factors and frequently also over advertising claims. The influence of universities administering patents is commonly in the direction of soundness and conservatism.

There is still an additional factor of importance, and this applies not only to university owned patents but also to those which are the property of adequately equipped pharmaceutical houses, and that is the prevention of the improper exploitation of medical products by companies which are not constituted, either scientifically or ethically, to market medical preparations.

It is perhaps unnecessary for me to state that I am convinced of the wisdom of universities, including medical schools, adopting a definite patent policy sufficiently broad in its scope to include the taking of patents by medical members of their staff as well as by others. When I say "definite" I do not mean inflexible because some differentiation I believe needs to be made between discoveries which are entirely the result of the universities' efforts and those which have been made possible by joint work with some one else, such as an affiliate in the pharmaceutical industry.

Various suggestions have been made from time to time of a central repository of research funds and patents. That there is a need for such a central organization for the administration of patents or that it is practically workable, I am not convinced. It seems to me that such an undertaking would be attended with many troublesome complications. Such a bureau might be of interest to a certain number of educational institutions who do not have the machinery, or who do not care to set up the machinery, for the administration of patents. Broad control of university patents by a central body would in my opinion have the effect of pushing industrial and educational institutions apart in their research efforts. The last decade has witnessed a steady growth in cooperation between research workers in universities and colleges and the constantly improving research departments associated with industry. The centralization of university patents would have the effect I am sure of removing much of the incentive toward this type of cooperation and forcing the industrial research laboratories to be competitors instead of co-workers of the investigators located in university centers.

A more constructive step in my opinion would be the formulation of certain general principles which would lead interested schools, including colleges of medicine, to take a positive rather than a negative attitude in the matter of patents and which would lead them to develop a sound patent policy. A broader interest on the part of medical schools in patents would be of great service both to medicine and the public welfare. This does not require any centralization of patents but only a crystallization of sound guiding principles.

DISCUSSION

MR. R. A. NORTON (Calco Chemical Company, Inc.), Bound Brook, N. J.: Mr. Lescohier spoke of the lack of danger of monopolies. That is something which is much in the public eye at the present moment. In dealing with medical patents there are two kinds of monopolies. One is a monopoly which would prevent free distribution or distribution at a reasonable cost to the patient. The other is a monopoly which determines who shall produce. Those two monopolies are different in their effect on human welfare. I don't believe there are any of us here today who would not agree that an abuse of the first monopoly is a very serious thing. A medical patent under no circumstances should be used to keep a remedy from human beings suffering with disease. A monopoly of the second class, which is of the type which is partially affected both by the Scarlet Fever Committee and by the Insulin Committee, and others, determines within limits who is going to manufacture, and that kind of a patent monopoly is not necessarily to be con-

trolled with the same degree of sharpness as the first kind. I got no impression that Mr. Leschier drew any distinction between those two kinds, and I think a real distinction exists, and one of real importance to social welfare.

DR. AUSTIN A. HAYDEN (Secretary, Board of Trustees, American Medical Association), Chicago: Medical patents are not all necessarily medical. We have been talking about foods, drugs and biologicals. I am interested in another line of patents that comes close to the welfare of the public. I refer to the patents or at least the patented articles that the Council on Physical Therapy has to deal with. In particular I think of the patents that exist on hearing aids and other mechanical contrivances. I believe these are subject to many of the considerations that have been spoken of here this morning in the matter of control, in the matter of the application of their use to the public welfare and, in this particular instance, to the use of handicapped groups of the public.

THE PUBLIC'S STAKE IN THE ADMINISTRATION OF MEDICAL PATENTS

EARL SHEPARD JOHNSON, A.M.
Assistant Professor of Sociology, University of Chicago
CHICAGO

I should like to beg leave at the outset to change slightly the wording of the topic under which my remarks are to be made. For "the public's stake" I should like to substitute "society's stake." The term "the public" connotes an informed group of persons able and willing to discuss the pros and cons of any problem lying within the field of social policy and social action and which develops, through this discussion, a more or less clearly articulated opinion or consensus. In substituting the term society for the term public I am thus enabled to speak in the interests of those who are neither informed nor articulate about the particular problem under discussion today but who are nevertheless directly affected by the public policies of both private and public agencies no less than their fellows who are more capable of formulating an independent judgment. I assume then the role of spokesman for this larger collectivity.

May I now present what seems to me to be substantial evidence that society does have a stake in and therefore is entitled to the maximum benefits of medical inventions and discoveries. First I would submit the proposition that invention is essentially collective or social rather than individual in nature. This theory denies, of course, Carlyle's "great man" theory of the nature of social change. In support of this social theory of invention, which I feel does not need lengthy elaboration here, I quote Dr. Bernhard J. Stern,¹ outstanding authority in the history of invention. "Medical discoveries and inventions, whether they be in the descriptive field of anatomy, in the diagnosis of causal relations between pathogenic micro-organisms and a specific disease, in the realm of immunology or in surgery and therapeutics have not been made suddenly but have been preceded by a multitude of preliminary and progressive steps which in turn had their antecedents. This principle applies without exception even to those medical discoveries and practices which are popularly considered as the result of the epoch-making work of some individual." Stern cites, by way of illustration, that the contribution of Vesalius was "a combination of humanist intellectual activity and the new naturalist art" for, as Professor Charles Singer has expressed it, "until these two had come together there could be no Vesalius [but] when these two had come together there had to be a Vesalius." The evidence is thus clear that, in the history of medical invention, those who have turned the magic key to unlock doors leading to new medical advance have been indebted to many others who worked to produce the materials for and helped to forge the key itself. This theory does not, of course, deny the importance of the rôle of the unique individual through whom the invention came to its final formulation. It does however seek to put the inventor in the perspective of his

cultural setting. Perhaps the central idea here may be expressed in the dictum that, in the realm of organic life, "all life comes from life"; in the cultural realm the dictum is that "all culture comes from culture." In both cases the doctrine of spontaneous generation is denied. The conclusion then follows that, since medical inventions are essentially cultural rather than individual in origin, they belong to the whole society and through this fact society establishes its claim to their widest and most proper social application.

My second proposition is that the ultimate end of all science is the benefit of mankind. The present confusion on this point is due to the failure to distinguish between pure and applied science. While all science must ultimately justify itself by its contribution to human well-being, each scientist must, in order to do proper scientific work, be motivated only or primarily by a devotion to scientific truth and any considerations which cause him to deviate from striving for that goal are to be rejected as destructive of scientific progress and finally of human progress. Society has then a priceless stake in science and will benefit from it in the measure that the most favorable environment for its development can be assured.

My third proposition is that society has a stake in the maintenance of the proper motivation of research activity, an interest closely related to the problem of the ultimate end of science. It will be helpful, in the elucidation of this proposition, to make a distinction between academic research and industrial research. While the former is concerned with the increase of the body of fundamental knowledge without any immediate thought as to its practical application, the latter is interested in the development, to a practical end, of the fundamental discoveries which the academic laboratories may be expected to furnish. But medical research differs from both of these in the respect that its ultimate aim is the provision of knowledge which will find application in the relief or the prevention of human sickness and suffering.² Academic and medical research differ, then, from industrial research in the character of their motivation. The first two, it may be properly said, have a scientific and service orientation respectively, while the third, at least so far as industrial research entrepreneurs are concerned, has an essentially commercial orientation. (I should make it clear that I do not mean to impute base and nonprofessional behavior to the activity or motivation of the industrial research scientist.) It is society's concern that there be no invasion of profit seeking into the first two types of research activity. The survival of a truly scientific tradition depends then on society's insistence that the highest professional standards be maintained in these fields.

Finally, society's stake in medical inventions lies in the generally agreed on proposition that health should not be a commodity dependent for its widest possible distribution and enjoyment solely on the ability to pay a price for it. This is tantamount to the affirmation that health is essentially a public utility. There is suggested here the dichotomy of vendability and serviceability, set forth so ably by Thorstein Veblen in his *The Theory of Business Enterprise*. Society's concern in the fields of all medical and therapeutic commodities is that the chief desideratum shall be that of their serviceability.

The question may now be raised as to the nature of the present policy or policies which have to do with the patenting or nonpatenting of medical inventions and, in the former case, to the nature of the administration of medical patents. And next, one may ask, What are the consequences for public welfare of the various present arrangements? To a brief consideration of these two questions I should now like to turn.

Concern about the problem of medical inventions, the multiplicity of divergent and in many cases conflicting policies concerning their control or noncontrol, would seem to warrant the conclusion that the present state is one characterized, on the whole, by an absence of uniformity, cooperative endeavor and rational integration. *Laissez faire* or at best a slightly attenuated variety of it would best describe the situation, for there is little evidence of a consistent and clearly formulated professional policy in the matter of the administration of medical inventions and discoveries.

ORGANIZATION SECTION

JOUR. A. M. A.
JULY 29, 1939

But perhaps the validity of the patenting of medical inventions ought first to be established. Its validity would rest, as I see it, on the simple proposition that in the absence of a patent right there is no legal provision for control, and control would, it seems to me, be particularly indispensable in the field of therapeutic agents. The question is not so much whether medical inventions and discoveries should be patented or not patented but rather it is one concerned with the problem as to whether individual or collective control of these patents would make for the greater public welfare. Finally, on this point I should like to remark that objection to the patenting of medical inventions, either by individuals or by organized groups, on the ground that such action would violate traditional medical ethics would, if the case for its social desirability is established, be confusing means with ends. Efficiency is not, of course, of itself ethical but efficiency as it plays a means role always has ethical effects.

Certain limitations prejudicial to the greatest public welfare appear to attach to the patenting of medical inventions by single individuals. Perhaps of greatest significance among these is the fact that only in the rarest instances would the individual inventor have sufficient resources to defend his patent in the courts. Patents must be policed. This is not a nice fact but unfortunately it is historically true in those instances in which a medical patent was contested for as a medium to monetary profit to the manufacturer. Another limitation which follows from individual patenting is that the formulation of a public policy with respect to the whole problem of patenting and patent administration is thereby rendered all but impossible. Furthermore, the fact that individual control may rest the patent and the rights which it confers with a good and wise person does not, for me, make a totally valid case. Society does need men of good will, but its proper integrity is better guaranteed when men of good will are organized to effect a planned and rational administration of their high purposes. Such a proposition would dictate that the control of medical patents should be vested in institutional rather than in individual hands.

Finally, both the logic and the desirability of institutional control of patents follows from the nature of the process of invention itself. Note that I do not question individual control on the ground that inventors in the field of medical discoveries are prompted by the desire for personal profit. It is all but axiomatic that patents, when they are sought by individuals in this field, are sought for the licensing power to protect society against the exploitation of the fruits of their research.

To invest the universities, in whose laboratories the greater part of scientific medical research is carried on, with the administration of patents would be contrary to my conception of the proper function of the university. It is the custodian of property only so far as it is immediately concerned with the administration of its central function, namely the pursuit of knowledge. As Dr. Morris Fishbein has pointed out in a recent issue of THE JOURNAL, for the university or academic research institute to assume the role of patent administrator might result in changing their tax-free status. The disastrous fiscal consequences alone of such a transition would more than defeat the gains made in the field of patent administration by this method. Dr. Fishbein has also called attention to the fact that such an arrangement might conceivably introduce a harmful competitive element that would certainly not improve the cooperation which has characterized the relationship between academic scientists and which is responsible for much of the progress which scientific inquiry has made.

This extremely sketchy and incomplete statement of the consequences to public welfare of the present practices in the field of medical patent administration brings me to the question of an alternative program. The fact that I have made no reference up to this point to such plans for patent administration as are represented by the Wisconsin Alumni Research Association, the Insulin Committee of the University of Toronto and many others following their general pattern is one of which I am aware. These organizations represent, by and large, the best answer to date to the problem of the administration of medical patents for the general welfare. They combine

the merit of constituting institutional rather than individual mechanisms for control and, furthermore, if I understand their organization correctly, they relieve the university administration of extending its efforts into fields not properly its own. Their chief limitation lies, as I see it, in their multiplicity and that fact in the lack of an integration of their activities. perhaps even more germane to the problem is the fact that the scope of their operation is limited to medical invention only in specific institutions and hence does not comprehend the total field of inventive activity in medicine. It is, then, the contribution which the integration of the administration of medical patents could make to science and through it to an expanding public welfare that is, I believe, the paramount need.

While I do not now propose to draw up minute specifications for an organization whose concern with the administration of medical patents would be national in scope, I should like briefly to indicate the function which such an institution might conceivably perform as well as to offer a few suggestions for the general pattern of its structure.

First, such an institution might be conceived merely as a device for integrating the work of the various existing medical institutes, committees, foundations, university research activities and the like which now undertake to patent and license medical inventions. So conceived, it would serve a function similar to that of the clearing house, providing for such important matters as uniformity of procedure, standardization of patent practice, coordination of research and other relevant activities. In this role it would not disturb the present scheme of patent ownership but would act chiefly in a supervisory and counseling capacity looking toward the most effective administration of the patenting of medical inventions.

A somewhat more comprehensive and ambitious conception would be contained in a proposal to vest in one single national body all the functions now being performed by the existing patent-administering organizations in the field of medical research. Such a plan would of course involve legal complications of the magnitude of which I am quite aware. But whether the national administration of medical patents would follow the first or the second pattern of organization which I have sketched, it would I feel greatly facilitate the progress of medical research and in turn maximize the social benefits from it through a rational administration of medical patents. Having suggested two general types of organizations for the administration of medical patents on a national scale, I should now like to indicate some of the merits which I feel inhere in this approach to the problem under discussion. The better equip it to put medical patents to work in the interests of the public welfare in a fashion superior to that which local or regional bodies could do, to say nothing of the superiority of both national and local organizations over the activity of single individuals in this respect. Furthermore the national body could afford an adequate and competent staff of technical, scientific and legal experts, all of whom are indispensable to the proper placing, policing and administration of patents. Its capital resources, created by the method which would seem most feasible and desirable, would be greater and, because of the national scope of the field in which it would be put to work, would be more effective dollar for dollar than the capital of the smaller and scattered organizations which undertake the task of the administration of medical patents. The organization should also be able, because of its larger capital resources, its larger and more expert staff and its national character, to make available data on such problems as manufacturing and marketing, which should be superior to that which the existing patent-administering organizations can furnish. Perhaps more important would be the prospect of its more effective supervision of the conditions under which the inventions under its administration were produced and marketed. In short, it would have all the merits and advantages which a national rather than a local organization has in the administration of a field which is by its nature national rather than local.

As to the question of the staff personnel in such an institution I should feel that its professional make-up would be the function of a reasonable understanding of the nature of its

task. This would dictate that it be composed of persons with the requisite skill and knowledge in the fields of medical therapy and research technics and in the equally important field of institutional administration and management.

While the primary function of such a national organization would be the administration of medical patents, it might properly, though as an item distinctly secondary in importance, perform a useful and presently needed fiscal purpose. It might license patents under a provision which would allow it to participate in a share of the profits of the concerns marketing its patents. Such participation might be sufficient to provide only for the overhead costs of administration. This would permit its organization with considerably smaller capital resources than if it did not share in the profits. But its participation in the manufacturer's profits might be of such a nature as to create additional resources which would be allocated to the member institutions and used by them in the support of their own research activities. In an economy in which the community is facing increasingly heavier tax obligations for the support of basic social services, the amount of tax money available for the subsidy of scientific research may not keep up with the increasing demands for its extension. On the other hand it is not to be denied that the prospect for the continuation of the endowment of scientific research by private gifts could be brighter than it is. Facing such a situation, the provision for research funds through participation by the patent administering organization in the profits from the manufacture of therapeutic commodities may not be entirely beside the point. The allocation of such earnings to research institutions would be made on the basis of the earnings of the inventions which had come from the fruits of their research activity and would be administered through the machinery of these otherwise autonomous member organizations. No prizes or returns would come to individual research workers, and their high professional pride would be the factor which would keep the laboratory free from any suspicion that it had become a party to the commercialization of science. The individual research workers whose labors resulted in a patented invention would have to seek their rewards through professionally adequate salaries and the knowledge that they had made an important contribution to the cause of public health.

In conclusion I should like to say that in the field of public health there must be no such contradiction between production and consumption on the one hand and the rights and duties of the individual and society on the other hand, as there is in certain other fields of endeavor today. The ultimate purpose of such an organization as I have suggested would be to stimulate and guard by rational methods the evolution of the consumptive art for the greatest possible good to both individual and group welfare.

DISCUSSION

MR. CARL S. MINER (Miner Laboratories), Chicago: I have been interested for a good many years in this very problem, not specifically with respect to medical inventions but with respect to university inventions applicable to industry, and I have for the first time heard made publicly what seems to me an adequate suggested solution. Initially, I believe the research foundation of the individual institution was a thoroughly adequate method of handling this problem. Latterly, I have become convinced that that is not the ultimate answer. At least occasionally there is some institution that has a research result that should go into the field of industry and which probably should make some return to the university research funds, but it is all too true that a foundation set up to handle such a single invention might find itself searching for duties to perform at a later date, and perhaps such a situation might result in involuntary pressure being put on the research group of that particular school to produce industrially useful results, which is something to be deplored by all of us. If a national institution were available to which such a relatively small school might take its completed research for exploitation, it would seem that it could answer the question so many of us have been worrying about, and I hope, as one result of this conference today, some group will adequately consider the possibilities of the suggestion Professor Johnson has put before us so ably.

DR. STUART MUDD (Council on Pharmacy and Chemistry, American Medical Association), Philadelphia: I would like to say a word from the point of view of the individual laboratory worker as to how welcome such an institution as Professor Johnson has mentioned would be to us. The present lack of any policy, or any ethic, really, to guide us when we have something that we feel is useful, or anybody in our own institution whose responsibility it is to advise us and take hold of anything worth while and do the constructive thing with it, is a very serious matter. We are floundering. We don't know what to do. If we had some institution of this sort that we could trust, that could advise us wisely and take hold of the things that are developed in the laboratories and use them ethically and for the good of science, and bring some return for the subsidizing of scientific research, it would be the greatest comfort to the research worker. I think I can say that with a great deal of assurance.

DR. R. E. DYER (U. S. Public Health Service), Washington, D. C.: In the discussion so far there are some things that stand out somewhat clearly, and one of them is the possible difference in attitude of a government agency, or an institution that is supported by tax funds, in comparison to a manufacturing establishment or to an individual. It seems reasonably clear that the policy Dr. Long outlined this morning as one in process of development for the National Research Council might apply to one set of institutions or to one group of men, but not be at all applicable to another group. It brings out the difficulty of establishing any general policy to handle all particular questions. Something along the line that Professor Johnson has just suggested may prove a satisfactory solution, in that such a body could be empowered to handle each individual question on its merits, determine the patentability of a discovery, the remuneration of the discoverer and the implementation of the patent for the benefit of the public.

DR. MORRIS FISHBEIN (Editor, THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION), Chicago: The fact that such discussions are continuing before this organization, before the National Research Council, before the American Chemical Society and before many other groups should indicate that the present situation is not satisfactory. The fact that there are constant allusions to interference with research in universities, in state health departments and other places would indicate that probably from time to time there has been interference with research. The fact that time and again universities have been accused of being interested primarily in the amount of income to be derived from patents rather than in basic research would indicate that at least a considerable number of people have the view that such an interest is occasionally manifest. Obviously, discussions will go on until some satisfactory solution is found of the problem of administering medical patents primarily for the public welfare. That duty we owe to society, particularly in relationship to the prevention of suffering and the control and treatment of disease. I do not know the answer to this question any more than any one else knows it. If an answer is to be found, aside from government control and administration, it must be found in some voluntary activity in which all of those who are concerned, including the individual physician, the university, the manufacturer and all other groups concerned, will come together and work out a mutually satisfactory solution which protects the rights of the inventor, the manufacturer and the university and which at the same time keeps primarily in mind the rights of the patient and of the public. Such a voluntary agency must be formed on a national scale, with sufficient strength and force to be able to administer such patents for the good of all. The suggestion made by Professor Johnson does not appear to be sufficiently worked out in detail to satisfy every one, but sooner or later it will be necessary to establish some such body. The fact that the National Research Council has seen the desirability of a corporation for the administration of such patents as come under its control would indicate their belief that an organization of that type is necessary. We are not here to adopt today any definite conclusions. We are merely here to study a trend. To me it seems that the trend is going to be toward the formation of a national organization for the administration of medical patents in the public interest.

DR. J. C. MORRELL (Universal Oil Products Company), Chicago: As I understood Mr. Johnson's thesis, it takes care of the administration of the patent so far as the public is concerned. I didn't quite understand how the individual inventor fits into this picture. The last thing I got was that, preferably, he should be a salaried employee. I am sure that such salaried employees of an organization of that kind would make only a small percentage of the contributions to medical science and that Mr. Johnson's proposal is not a general solution of the problem from this point of view. I would like to ask Mr. Johnson just how the individual inventor will be taken care of by the method which he suggests.

DR. ESMOND R. LONG, Washington, D. C.: I rise merely to make a minor correction in Dr. Fishbein's remarks. I believe the Research Council would welcome an organization in which we all had thorough confidence to take care of the difficult problems that come before us. As I mentioned this morning, we are exploring the possibilities with such an organization. The one I mentioned is not organized for operation on the scale necessary for such a task as Professor Johnson has visualized but has made definite progress in that direction. I am presenting no special brief for this organization. It has been useful to us for certain substances; you will recall, however, that the Council's resolutions which I read to you stated specifically that the council could take advantage of this organization or any other set up for a similar purpose. The organization to which I refer is the Research Corporation of New York.

DR. ROGER I. LEE (Harvard Corporation), Boston: At Harvard University we have had a good deal of experience, as have all universities, with regard to these perplexing patents. In the first instance, to be specific, we had the so-called Drinker patent, the Drinker respirator, which was devised by Mr. Phillip Drinker, who was a member of the School of Public Health and not a doctor. That was patented and led to a great deal of grief on the part of all concerned, including the Drinkers, the holders of the patents and various other people. The next important step in our history was the formation of a Committee on Anemia to take charge of the work of Minot, Murphy and others with regard to the so-called cure of pernicious anemia. That committee of the Harvard Medical School operated, not entirely satisfactorily perhaps, but still it operated without a patent and, on the whole, the advantages seemed far to outweigh the disadvantages. The university has scrutinized with a great deal of care all the pros and cons and, without repeating the arguments one way or another, and particularly with the utmost friendliness for industry, because it feels that the university should not go into active competition with industry. If the university, in its position, goes into active competition with industry it is unfair competition, it seemed to us, with a good many advantages on the part of the university. Finally the university made the following ruling. I go back to May 28, 1934. The president of the university communicated to the Corporation the following votes of the faculties: "In the opinion of the Faculties of Medicine, Public Health, Engineering and Arts and Sciences of Harvard University, the patenting by members of the university of discoveries or inventions bearing on matters of health and therapeutics is undesirable." Those were separate votes of each of those different faculties. These several faculties recommend that the president and Fellows of Harvard College adopt the following rule: "That no patents primarily concerned with therapeutics or public health may be taken out by any member of the university, except with the consent of the president and Fellows, nor will such patents be taken out by the university itself unless they be dedicated to the public. The president and Fellows will provide legal advice to any one who desires steps to be taken to prevent the patenting by others of his discoveries or inventions." It was voted to adopt this rule and that the policy of the university with regard to patents is given in the following statement: "In the opinion of the Faculties of Medicine, Public Health, Engineering and Arts and Sciences, the patenting by members of the university of discoveries or inventions bearing on matters of health and therapeutics is undesirable. The president and Fellows of Harvard College, therefore, have

adopted the rule that no patents primarily concerned with therapeutics or public health may be taken out by any member of the university, except with the consent of the president and Fellows, nor will such patents be taken out by the university itself unless they be dedicated to the public. The president and Fellows will provide legal advice to any one who desires steps to be taken to prevent the patenting by others of his discoveries or inventions." Then a year later, May 20, 1935, it was voted to adopt the following statement for the guidance of members of the university in matters relating to discoveries or inventions primarily concerned with public health and therapeutics: "In connection with the policy of the university to make available to the public discoveries or inventions primarily concerned with public health and therapeutics, there is evidence that in some cases it may be necessary to take out a patent and dedicate it to the public in order to prevent others from obtaining a patent for their own benefit. Accordingly each member of the university is asked to report any such discovery or invention made by him to the dean of his faculty, with a recommendation, as to whether it should be patented for the above purpose, in order that if necessary steps may be taken to obtain and dedicate the patent. If the member making any such discovery or invention believes it should be patented for any other reason, he should so report to the dean, giving his reasons in full so that the matter may be submitted to the Corporation for decision."

DR. H. L. RUSSELL (Wisconsin Alumni Research Foundation), Madison, Wis.: I don't think, Mr. Chairman, there is anything I can contribute, representing the Wisconsin Alumni Research Foundation. I believe the principles laid down by Professor Johnson have merit and, from the point of view of unifying and integrating work of this character, something of that sort might be worked out. That probably will not become effective immediately and, in the meantime, the several foundations that are interested in matters of this sort probably will continue to function, I presume.

DR. JAMES M. NEILL (Cornell University), New York: In all discussions on methods of administration of patents, it is well to remember that the opinion in this country is not unanimous that it is either desirable or necessary to take medical patents at all. To me there seems to be only one argument to indicate that patenting by universities or endowed hospitals would ever be desirable; that is, the possibility that discoveries made there might subsequently be patented by other people. If that one objection could be removed (and perhaps the danger from that source is overemphasized), I believe there would be no question that all schools and hospitals would gain more than they would lose by the simple rule that they do not patent anything under any circumstances. At any event, I think the setting up of a large central body like that proposed by Professor Johnson would be a bad thing to do because the existence of a board of that sort would be more likely to increase than to decrease the present tendency toward too many patents.

MR. EARL S. JOHNSON: If I understood the gentleman correctly, his question had to do with what provision this institution, which I have sketched in very brief outline—what service it would perform for the lone wolf.

DR. MORRELL: Both the lone wolf and the individual working in some institution outside of this proposed national institution.

MR. JOHNSON: I should think the member bodies of the national institution would be various types of research organizations. They might be research institutes; they might be the university laboratories themselves. With reference to the lone wolf inventor, I thought he had generally gone west with the buffalo. I may be misinformed about that. I think he is of relatively little significance, although his contributions may be very important, still. As I read the history of social change, I see increasing institutionalization of the whole process of invention. I should, of course, want to take account of these rare birds who are still about and would offer them under some definite prescription the opportunity for their researches being piped into this organization to get from it the kind of services it could render. I have only this other thing to say, Dr. Lee, that either I have made a very startling remark, which

ORGANIZATION SECTION

425

is profound in its significance and is so brilliant and intelligent that you gentlemen, who are both profound and intelligent, have seen the wisdom of it; or it is a very ordinary and naive one which is as old as the hills, and I go back to my colleagues heartened and warmed and to say that under some circumstances even what a sociologist says makes common sense.

MEDICAL PATENTS AND THE LICENSING SYSTEM FROM THE POINT OF VIEW OF THE COUNCIL ON PHARMACY AND CHEMISTRY

TORALD SOLLMANN, M.D.,
Professor of Pharmacology and Materia Medica, Western Reserve
University School of Medicine
CLEVELAND

The Council on Pharmacy and Chemistry does not have fixed views on this subject. I give you my interpretation of what I think the Council views are as I have heard them expressed at various times.

The Council has an open mind on the subject of patents. It realizes, as you all do, that this is an extremely complex problem that at present, I think, is not amenable to a very simple solution. We may hope to work toward one by experimentation along some of the lines that have been discussed, and I think perhaps, in the end, we shall arrive at something that is fairly workable, but it is perhaps lucky for us that we do not have to come to a decision today.

The Council on Pharmacy and Chemistry has for its function the advising of the American Medical Association regarding drugs offered for prescribing by physicians. Being new, the Council, especially as it applies to manufacturing houses, think all of us, when we think about the subject with a little knowledge, realize that the introduction of a new substance by a manufacturing house is an expensive and a risky process which, in general, could not be undertaken unless there was some degree of monopoly granted. Recognizing that as applying to manufacturing houses, the Council also has to recognize it as applying to other individuals. We have to accept the fact that patents are taken out by universities and are taken out by individuals.

It does seem to me, however, that universities do have a special obligation to the public in view of the way in which they are supported by the public, and that the members of universities have obligations both to the public and to the universities, because the very fact that they can work at all is due to the universities and to the public. Therefore they are not entirely, to my mind at least, in the free position, as regards manufacturing houses need to consider in this respect, I think, only whether the thing is good policy. In the case of the universities they have to go a little further and have to consider whether it is fair to the conditions under which they exist.

While the Council does not combat patents as such, it has been in position to observe perhaps more clearly than some others that there are tendencies in patenting that are unfortunate. I think that most of those have already been brought out but I do wish to discuss them a little more. They are unfortunate in the case of universities, and very much more in the case of individuals.

The whole matter, I think, begins with the Patent Office. After all, when patents were instituted it was not medical inventions that were in the minds of Congress but particularly mechanical inventions of various kinds. The whole Patent Office is set up for that and not for medical patents, and considerable difficulties arise from that, from a want of understanding, for one thing, of what is involved in medical patents, and also from want of understanding that the situations are not entirely comparable. The Patent Office is geared to the industries and not to the practice of medicine.

The patent laws were instituted, as we have been told, to promote useful inventions. Notwithstanding what has been

said, I think it is on the whole questionable whether they have promoted very greatly invention in medicine, and especially in universities. I believe all the inventions in medicine that have been made, that are worth anything at all, would have been made just the same and at just about the same time if there had been no patents in existence and no patent protection. They might not have been popularized so fast, but that is another story. But as to invention, I do not believe they have had much influence.

Again, the intent of the patents was to promote the disclosure of secrets and again I doubt whether any material secret in regard to medical matters has been disclosed because a patent could be obtained on them. I think they would have been disclosed, if they had been invented, in just the same way as they were disclosed under the patent.

Then, again, in order to be patented the invention should be new and it should be useful. As Professor Johnson has very well brought out, when we delve into the newness of the things on which patents are issued a great number of these inventions are simply putting a capstone on what other people have done, and with very unequal justice. It happens not infrequently that the people who have done the fundamental work have been the kind who did not care to take out patents, and then some one comes along and adds just a little to it and takes out a patent.

On the matter of usefulness, a medical invention is not useful until it has been tried out by unprejudiced clinicians and pharmacologists. As soon as you have a monopoly there is, in the first place, a tendency to have a prejudice and, in the second place, the secrecy that is demanded before a patent is obtained works against getting a wide experience with the substance. It works in just the way in which it is not intended to work.

It has been mentioned to us that patenting by universities instead of aiding invention tends to prevent it, that it interferes in ways sometimes intended, perhaps more often not intended, with other people working at the subject. It tends to keep matters secret until the patent is obtained which, if known, would give some one else an idea to advance further.

There is a particularly objectionable type of patenting, as I see it, that consists in patenting the mixing of well known drugs, with the claim that a new action is obtained. Very often those drugs exist together in nature, have always been used together—unintentionally, it may be—but it does seem to me that nothing is furthered by patenting what nature has provided without a patent. On the other hand, as soon as you patent the prescribing together of things you interfere seriously with what should be the privilege of the physician, that of prescribing things together as he may wish to prescribe them. He may not want to prescribe forms that the manufacturer puts up, but as soon as a patent is obtained on mixing things he cannot go further.

The argument that is made for financing further research by patents has very serious drawbacks. Of course, we all understand that the support of research in universities is diminishing, and we may have to wait some time until another way of financing is found. But as soon as we introduce a profit motive, whether it be for the individual or whether it be for the university, we introduce a motive that, it seems to me, kills off a good deal of that for which the universities have stood and are standing. Research in universities should be free from money motives. As soon as the money motive enters—whether it is for the support of further research or the football team, makes no essential difference—the university laboratory becomes a commercial laboratory, usually not as well organized for commercial research as commercial houses can organize it. It is apt to be a second-rate commercial laboratory.

I think if there is any justification—and we all know there is—for university research, it is that the profit motive is kept away from it, so that it can go after fundamental things which other people do not feel as free to go for. If this is the only way in which universities can be saved, that is, by making money out of research, then it becomes a grave question as to whether they are being saved as universities or are not being made into something else, something that may not be worth saving.

Now comes the argument of control of abuses, and that has a good many very telling points which make it a subject on which I, for one, am not ready to decide. They have all been brought up, many of them at least: the matter of piracy, the matter of preventing low standards, and so on.

I think Professor Johnson is on the right track there: if the universities patent things to protect the public, it would be better to give the profit to somebody else and so be quite sure of their motive.

Another argument is that without this protection it would not pay any one to market the invention even though it would be free to manufacture. We do have some outstanding examples on the other side. The antianemic principle of liver certainly went across without patenting; so did sulfanilamide. If something is really good enough there is no need to promote it by a patent or to protect it by a patent. The laws as they now stand would be sufficient for that. Of course, there are many things not quite big enough for that, and for them protection may be useful or necessary.

There is a related topic, not a patent but something that takes the place of it, the copyrighted name or trade-mark, which has not been mentioned. This device seems to defeat or at least evade the intent of the patent, of protecting a monopoly for a short time, by substituting an indefinitely prolonged protection. There may be cases for which seven years or fourteen years—whatever the time may be that a patent can be made to run by subsidiary patents, or what-not—may not be sufficient. It is quite possible, but it does seem too bad that it is necessary to evade a law in order to make it work. It would seem much better to legislate needed extensions of the patent rather than to go around the corner and try to accomplish the same thing in an entirely different way.

All these matters could be improved, no doubt, by improving the laws. As has been mentioned, perhaps, the patent law as a whole should be improved. It may be, as Mr. Hutchison mentioned, that there should be a special modification of the patent law applicable to drugs and devices, because they do have a special relation. Perhaps it would be well if the Patent Office had a special machinery for doing this and did not throw it over to people whose knowledge of medical matters is apparently not very great. I think probably more can be accomplished by the way in which the patent laws are applied and interpreted than has as yet been done. I think things are setting in that direction.

The financial reward of the inventor is not a direct concern of the Council but it is difficult to dissociate these matters. I think it would be very unfortunate if in universities there should be professors who make a large amount of money or indeed, any amount of money because they devote themselves to inventions, as opposed to another class who are equally able and who devote themselves to the proper business of the university. You have here the professor of mathematics, perhaps, who has no opportunity of making inventions, as against the professor of, let us say, pharmacology, who might have considerable opportunity for an income from patents. When you introduce the profit motive into universities, things go askew.

The views which I have expressed, while they may be shared by the other members of the Council, are largely personal. The Council does not control the law of the land; it has to work under the law and with it. It can, however, and does have its own standards, which are not necessarily the same as those of the Patent Office. And knowing, as I think it does, the problems of medicine and therapeutics more intimately, it should take some leadership toward improving the attitudes that pertain to medical patents.

Coming to the practical things, I think the measure our chairman has outlined as having been taken by Harvard is good. It sets up a presumption that one should avoid patents unless they are necessary. It sets up a machinery by which a disinterested body determines whether they are necessary or not, and it directly specifies that those who are concerned in taking out the patent, be it as individuals or as an institution, shall not have a profit motive in taking them out. Whether, beyond that, it is advisable to go to a national organization such as Professor Johnson outlined is an interesting

speculation at this moment, which holds a great deal of promise. It is nothing new, as the National Research Council has pointed out. There is even now an organization to which such patents could be turned over, but it is not primarily concerned with medical patents and for the reason with which I started, namely that medical and nonmedical patents are rather distinct things. I think, if one went ahead with this, it would be advisable to have a separate organization for medical patents.

DISCUSSION

DR. EUGENE F. DU BOIS (Professor of Medicine, Cornell University), New York: The minority point of view, it seems to me, is being brought out in this latter part of the discussion—such a view as that of the National Research Council, of Harvard University, of my colleague Dr. Neill, of Dr. Fishbein and of Dr. Sollmann. I can see how it is necessary for a university to take out patents in certain rare cases, very much as a nation might have to set up a defensive armament made necessary by the aggressive armaments of others, but in my opinion such patenting should not be used for the acquisition of new territory, no matter how fertile and desirable it might seem. I should like to emphasize an intangible subject, reputation, the most precious possession of any university, the only thing that really counts. It is quite conceivable that a university, in using a patent to get new funds for research work, might gain a few thousand dollars. It also might lose millions, not millions in dollars but millions in some other unit that measures reputation. The same thing might apply to the individual. Reputation is just as important to the individual as it is to the university, and if a man utilized the large amount of fundamental work that had been accomplished by others in his field and took out a patent he would be in danger of suppressing fundamental work done by his colleagues and he might not allot proper credit. He would be in danger of losing the one great attribute of the research worker; that is, his reputation for fundamental work in his own field.

MR. R. A. NORTON (Calco Chemical Company, Inc.), Bound Brook, N. J.: I merely wanted to make a brief statement amplifying the proposition that Dr. Sollmann has put up, that medical patents should be treated in a different manner from ordinary chemical or mechanical patents. Dr. Sollmann's statement, I am afraid, leaves the impression that that is not being done at the present time. I can state from my own personal knowledge, some of it painful, that it is. There is a very definite, fixed rule in the Patent Office today that the degree of invention required in a medical patent is of an entirely different order of magnitude from that required to support a mechanical patent. This last month a patent was granted, which I prosecuted, in which I had the greatest difficulty in persuading the Patent Office that the clinical evidence which satisfied the Council of the American Medical Association was sufficient evidence that the product was useful and not harmful, and it was only after extended argument that I convinced the examiner. Its standards today are high. It is handicapped only to the extent that it must deal with evidence which is submitted ex parte in the form of affidavits and is therefore vulnerable to any evidence which is not sincere. But that type of evidence is not as easy to get as it used to be. At present, that is a rule of the Patent Office, merely by commissioner's order and not by statute. Conceivably it might be changed. I don't believe it should be changed. If it is necessary in any one's opinion to have a statutory provision to keep this high standard, I think that would be one that few of us would have any objection to. With regard to the question of mixtures of drugs, to which Dr. Sollmann has referred, there is a very definite trend in the Patent Office today to refuse a patent on any mixture unless it can be shown conclusively—and it requires very severe evidence—that the combined result of the two drugs is more than the sum of their individual results and is a result which could not be predicted and would not be expected. I think, therefore, that the provisions Dr. Sollmann feels are necessary in order to protect medical patents are, to a very large measure, already in existence in the Patent Office, and I hope, for one, that the Patent Office keeps up the good work.

DR. F. W. SULLIVAN JR. (American Chemical Society), Washington, D. C.: The American Chemical Society appreciates very much the opportunity to be represented at this conference. Our society is actively interested in patent affairs and is cooperating through one of the members of its Patent Committee with the National Advisory Council to the House Committee on Patents. I am sure that our society will be very glad to continue its association with other meetings of this sort sponsored by your organization.

DR. ELMER L. SEVRINGHAUS (Professor of Medicine, University of Wisconsin Medical School), Madison, Wis.: It is obvious that much of our conclusion must be based on generalizations, and yet I think we were helped, especially this morning, by the concrete cases that were discussed, particularly with the scarlet fever and the insulin work. The one alternative to the patenting that has been mentioned seriously is the experience of the Harvard University group that the chairman has mentioned to us. I wonder, however, whether it would be out of order to ask that we have some further details about how that has worked out in the matter of control, the prevention of exploitation, and particularly in the uniformity of product—the product control. That is not a question that bears on only the antianemic material but I think, by analogy, has a great deal to do with the situation in the endocrine field, which is rapidly becoming chaotic because of the diversity of products, the different kinds of units, and so on. If this method of control without patent can operate to insure good product uniformity, I think it might help us in our thinking to know how it works.

CHAIRMAN LEE: If I may very informally answer that question as far as I can, of course there has been no attempt to control the antianemic factor. That has been thrown open to the public. The committee has simply advised in the progress of the work at the university. It has been willing to advise and to give all possible assistance and immediate data to any of the industrial houses that wanted it. There has been no attempt in this instance to exercise any control. It is the opinion of people who are close to the work that, on the whole, it has worked satisfactorily; that, on the whole, it has worked well with less hardship than would have occurred probably if it had been patented. It has resulted, as we all know, in great and active research on the part of many workers and many of the industrial concerns. Out of that has come, as by-products, a great deal of important data, some of which are very much more important than the actual preliminary liver work, and the work on the liver fraction which at that time was thought to be the underlying factor in the cure and control of pernicious anemia. Some of the work has been done in the Harvard Medical School but a great deal of it has been done elsewhere, and it has seemed to some of us that it was important that it should be done elsewhere because, after all, the work on the liver business was probably started in a great many places—probably not at Harvard University, although they happened on the real factor, which was the size of the dose of liver. Given a few months more, undoubtedly that would have happened somewhere else, and I am under the impression that it did happen in other places at about the same time that it happened at Harvard University. But there has been, I think, in the antianemic factor a tremendous amount of research activity and it seems to me doubtful—while this is just an opinion, nobody can prove it one way or another—that the same amount of research activity would have happened under any other situation.

DR. J. C. MORRELL, Chicago: I am going to risk getting up again on what I consider a rather important point, which is a technical question from the patent point of view, and that is if a university or other organization or even an individual wants to make discoveries for beneficent purposes without gain to itself and dedicates a patent, for example, to the public, this procedure may have undesirable results in that it permits a group of secondary inventors to come in and perhaps control the use of the product to the detriment of the public. I will cite an example: Take the case of sulfanilamide. If sulfanilamide had been patented and was not dedicated to the public for its free use because of the prior art it could be controlled

by a beneficent organization, which could permit its proper distribution and use without charge, if desired, by those groups or individuals who are qualified and should be entitled to distribute it. The use of the diethylene glycol as a solvent for sulfanilamide could not have been as widespread, with the dire results which followed, because it would have been dominated by the main patent; and the distributor would have been subject to suit for infringement. I think that is a point which is well worth noting, that merely dedicating a patent to the public will not protect the public, but the product should be patented and kept under some control to prevent these secondary developments and patents which may control the situation if the dominating or protecting influence of the primary patent is not present or has been removed.

MR. F. LORNE HUTCHISON, Toronto: I gather that Dr. Sollmann is not just quite sure in his own mind as to the extent to which the public interest needs protection through patenting. I think he is quite right; I don't believe this need is particularly frequent. Moreover, I think the United States is probably somewhat alone in the matter of possibilities of patent piracy. But I do want to give Dr. Sollmann one actual example of need that was demonstrated for patenting in the public interest: In 1922 insulin was first used clinically. There was no desire whatever on the part of Banting and Best, their colleagues or the University of Toronto to take a patent on insulin. Furthermore, we had not heard of patent pirates because under our law patent piracy is, I think, not possible, although of that I am not sure. But it was brought home to Banting and Best and their colleagues that, though insulin was only in the initial stages of its development and had not been perfected for clinical use, it was obvious not only that there would be great and urgent demand for the product but also that some material improvement in the product would probably be made quite soon, which improvement might be made outside the university by some party actuated by profit motives who might obtain a patent that could be administered purely for his own benefit or the benefit of his company, were the University of Toronto not to obtain a basic patent to which improvement patents would be subsidiary. Fear of the dangers of such a development proved within a few months to have been warranted. A material improvement in the process of preparing insulin was discovered. As this improved process was patentable, it could have developed that the whole world would have had to pay excessive tribute to the inventor of this process had there not been a basic patent standing in the way, and had our necks not been saved by a happy combination of other fortunate circumstances. It was only in these circumstances that it proved possible to avoid dangers which were originally feared and which easily might have actually materialized within a year of the first clinical use of insulin. I also agree with Dr. Du Bois that such instances are rare. As you can imagine, in the years following 1922 there were plenty of patentable discoveries made at the University of Toronto. It was not, however, until twelve years later that another patent was taken by the university. Whereas the insulin patent had two *raison d'être*, namely protection and control, this second patent was taken only for purposes of protection. It related to a machine which at that time looked valuable for use in reducing and preventing the incidence of silicosis in mines. Obviously, this machine might readily have been improved by some one who might take a patent on the improvement and collect excessive royalties from it. The university in these circumstances was advised that, as there might be a demand for this machine in all countries where there were gold mines, a patent should be taken in order to prevent any one from levying excessive tribute from either slight or material improvement of the machine. A basic patent was therefore obtained for dedication to the public through the offices of the Ontario Mining Association, which was willing to make rights to its use free to any proper person in the world who wished to use it.

DR. TORALD SOLLMANN, Cleveland: I quite agree with Dr. Du Bois and Mr. Hutchison that there are occasions when patents for the protection of the public are advisable; but, when the profit motive enters, those occasions undoubtedly seem more numerous than without the profit.

ADDRESS OF SENATOR ROBERT A. TAFT

AT LAYING OF CORNER-STONE OF DOCTORS' BUILDING, WASHINGTON, D. C., JULY 11

It gives me the greatest pleasure to say a few words at the laying of the corner-stone of the Doctors' Hospital here in Washington. Almost unique among similar enterprises of the present day, this building is being constructed entirely from private resources, without government assistance of any kind whatsoever. It is designed to provide 250 additional hospital beds for the District of Columbia, of a simple but efficient character, designed to reach patients who can pay approximately \$6 a day either from their own resources or as members of the hospital associations, which have been extended so widely in the District. It has been organized, and the money raised by doctors, to meet the local need for hospitals, in a city which is perhaps growing faster than any other city in the United States because of the increased activities of the government departments. I enjoy the opportunity of praising the initiative of the medical profession of the District in working out its own problems without lying down on the government.

To some extent the medical profession is subject to the same criticism which is often directed at members of the legal profession. The abler members of the profession are likely to become so busy in their own practice that they pay too little attention to the question whether the profession as a whole is covering adequately its whole broad field of public service. Because their own task is well done, they are likely to feel no great concern about the question whether the administration of law or the administration of medicine is serving the public and the country as it should. Of course this is only a generalization, for countless reforms in the field of law have been initiated by lawyers, and countless reforms in the field of medicine by doctors. Here today we see how constructive enterprises are carried through to success if a few men are willing to devote their time and energy to the task.

We have before us in Congress today the National Health Bill introduced by Senator Wagner, proposing to extend vast federal assistance throughout the field of public health and medical care. It appropriates, out of our growing deficit, approximately \$100,000,000 of federal money the first year, and gradually increasing sums thereafter, until in ten years it will cost the federal government more than \$400,000,000 and require the states to supply approximately the same amount. This money is to be distributed to those states which have adopted state plans in various fields of medical work. In general the character of the plan is left to the state, but the appropriation of money collected from all the states to those states which go along with the program forces all the states as a practical matter to adopt some plan in each one of the fields covered by the bill. Six categories of state activity are provided for, namely maternal and child welfare, handicapped children, public health work, hospitals, general medical care and sickness insurance. The bill has been strenuously attacked by many witnesses from the medical profession and is not likely to be pressed at this session, but I believe that in 1940 a federal medical program of some kind will be adopted. What form it takes depends largely on the medical profession. I am most hopeful that the doctors determine what comprehensive program can be adopted to improve the health of the American people, and that they propose a practical measure to assist that program.

The present bill seems to me needlessly complicated. Its administration will take place under three different federal departments. Every state must adopt at least six separate plans, and for each plan there is an advisory committee, so that the bill will create approximately 300 different boards, largely composed of laymen. Surely the federal health program ought to be consolidated under one head, and each state program ought to be worked out as far as possible under a single state department. The doctors feel very strongly, and I think justifiably, that, while the Wagner bill does not itself contain specifically a program of socialized medicine, it is proposed by those who favor socialized medicine and is open to the suspicion that it will afford a vehicle through which they may put their state-controlled medical care into effect. I feel confident that proper amendment of the bill can prevent such a result. We should be, above all, concerned that every patient retain the right to

select his own physician, so that the personal relationship may not be disturbed and the success of the individual physician may depend on his real ability instead of his political connections. We should be concerned that no great proportion of the doctors ever become employees of government. I see no reason why the present condition of individual service should not be preserved, even though we adopt the principle of federal financial assistance.

Undoubtedly the deficiency in medical service in many parts of the United States has been exaggerated in the report of the sponsors of the bill, but nevertheless there is a lack of such service, resulting principally from the poverty of millions of American citizens. Unable to pay for medical service, they find no service at all in some rural sections or they find the free service supplied by their cities or states inadequate or ineffective, and they may not be fortunate enough to receive any of the tremendous amount of charitable service provided by physicians themselves. Of course nothing is more important than health in meeting the problems of the average family and, if possible, it is even more important to those unable to pay for assistance than it is for those who are better off financially.

There are those who question the wisdom of any federal assistance in the health field, but, as in the case of relief and old age pensions, we have found that the states and localities have practically exhausted their financial resources in dealing with the established activities of government, like schools, roads and city services. They were unable to push on into the new field of assisting those classes who receive inadequate income, through relief and old age pensions. Most localities and states have undertaken health work but do not have the funds to make it universally effective. Some localities have never been able to undertake it at all. Assistance from the federal government in some fields is essential, and such assistance seems to me justified in the field of public health, provided it is in a reasonable amount to meet real needs in a sensible and economic manner.

The sponsors of the present bill seem to exaggerate grossly the lack of hospital service in the United States. Disregarding all private hospital service, they apparently plan a vast system of public hospitals to take care of everybody who would like to go to a free hospital. Any hospital plan should certainly encourage the construction of private hospitals and their use by public and private patients to their full capacity. It should encourage private plans of hospital insurance, which will assist the success of private hospitals and reduce the expense of operating public hospitals. The construction of this Doctors' Hospital here in Washington shows that a large part of our problem may be met without the pouring out of more millions from the federal treasury and without turning over to some state or federal official the entire determination of who shall receive hospitalization and when he shall receive it; and the hospital plan ought to be worked out deliberately to encourage philanthropic persons to invest their own money in the extension of private hospital service, as they have so liberally invested it during the past fifty years.

There is hardly a field in which there has been more sensational and continuous improvement than that of medicine in the United States. That improvement has been due to the brilliant, unselfish and industrious work of thousands of physicians. It is not their fault that incomes are unequally distributed and that efforts by local government to cover the entire field of health have been restricted by lack of resources. But now I hope they will take an active interest in seeing that the unequalled medical service received by most Americans is extended to the entire population. Their own interest and participation in the program will make it certain that it is not dominated by half-baked theorists or by those who believe in a totalitarian state, directing the lives and caring for the health of all its citizens through the mechanical and usually careless action of government bureaus. I believe a federal aid program can be worked out. I believe it can be much simpler and much more economical, and much more likely to preserve the essential independence of the doctors than the present Wagner bill. I believe it can be worked out with the assistance and cooperation of the doctors themselves.

MEDICAL LEGISLATION

DISTRICT OF COLUMBIA

Changes in Status.—H. R. 4732 and H. R. 4733 have been reported to the House with amendments, providing respectively for the issuance of a license to practice chiropractic in the District of Columbia to George M. Corriveau and Laura T. Corriveau. H. R. 6266 has been reported to the House, providing for the incorporation of certain persons as Group Hospitalization, Inc., the corporation to be authorized to enter into contracts with individuals or groups of individuals to provide for hospitalization of such individuals, to enter into contracts with hospitals for the care and treatment of such individuals, and to cooperate, consolidate or contract with groups or organizations interested in promoting and safeguarding the public health.

MEDICAL BILLS IN CONGRESS

Changes in Status.—The President has vetoed H. R. 3537, proposing to extend the facilities of the United States Public Health Service to active officers of the foreign service of the United States. The bill, the President said in his veto message, would open up a wholly new field of government medical and dental care for government servants and to establish such a government policy would in a short time involve "setting up of dispensaries and bed facilities in every place in the country where there are many employees of the government" (S. Doc. 431). S. 1540 has been reported to the House, proposing to increase the compensation of members of the National Advisory Health Council not in the regular employment of the government. S. 1899 has been reported to the House, providing for the detail of a commissioned medical officer of the Public Health Service to serve as assistant to the Surgeon General. S. 2420 has been reported to the Senate, proposing to authorize the Secretary of the Interior to cause to be made annual inspections and investigations in coal mines for the purpose of obtaining information relating to health and safety conditions, accidents and occupational diseases therein. H. R. 6076 has passed the Senate, providing for the registry of surgeons as staff officers on vessels of the United States. H. R. 6555 has passed the House, proposing to amend the law relating to the advance of funds in connection with the enforcement of acts relating to narcotic drugs, so as to permit such advances in connection with the enforcement of the Marihuana Tax Act of 1937. H. R. 6556 has passed the House, providing for the seizure and forfeiture of vessels, vehicles and aircraft used to transport narcotic drugs, firearms and counterfeit coins, obligations, securities and paraphernalia.

Bills Introduced.—Senate 2802, introduced by Senator Shepard, Texas, proposes to amend an act authorizing the operation of stands in federal buildings by blind persons. Under the present law a blind person is defined to mean a person having not more than 10 per cent of visual acuity in the better eye with correction. Such blindness must be certified by a duly licensed ophthalmologist. The pending bill proposes to define a blind person as a person having not more than 20/200 of visual acuity in the better eye with maximum correction or a person whose field of vision is limited to 20 degrees or less from the fixation point in all quadrants. The pending bill eliminates the requirement that the blindness must be certified by a duly licensed ophthalmologist. Senate 2862, introduced by Senator Wagner, New York, proposes to provide compensation for disability or death resulting from injury to employees of interstate carriers. The bill devolves on employers the duty to furnish such medical, surgical and other attendance or treatment, nurse and hospital service, medicine, crutches and apparatus for such period as the nature of the injury or the process of recovery may require. The term "injury" is defined to mean "accidental or wilfully caused injury or death arising out of and in the course of employment, and such disease or infection as naturally or unavoidably results from such accidental injury, and such disease or infection as arises out of employment." H. R. 7243, introduced by Representative Starnes, Alabama, proposes to make appropriations for public works projects. It

provides that not to exceed \$50,000,000 shall be allotted to federal agencies for federal construction projects, to include specifically projects for hospital and domiciliary facilities of the Veterans' Administration and projects for hospital, quarantine and laboratory facilities under the Public Health Service in the Federal Security Agency. Other funds are to be utilized, it is proposed, in making loans or grants to public agencies and to nonprofit corporations for the construction, improvement or extension of hospital facilities, for sewage treatment or disposal plants and for the elimination of pollution in streams.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Fund for Study of Respiratory Diseases.—Mr. and Mrs. Ellis Levy, Beverly Hills, have given \$10,000 to form the Rose Lampert Graff Foundation at Cedars of Lebanon Hospital, Los Angeles, for the study of respiratory diseases during 1939. Dr. Jacob J. Singer, Los Angeles, is director of the foundation, which is a memorial to Mrs. Levy's mother. The foundation was organized as a corporation Dec. 14, 1938, and plans are now being considered by the donors to continue it for five years.

Society News.—At a meeting of the Alameda County Medical Association in Oakland June 19 the speakers, all members of the staff of Merritt Hospital, included Drs. William H. Sargent on "Treatment of Skin Cancer with Unfiltered X-Ray"; Frederick E. Blume, "An Unusual Abdominal Tumor"; Lloyd E. Kindall, "Surgical Removal of Renal Calculi," and John N. Ewer, "Trichomonas and Yeast Vaginitis."

DISTRICT OF COLUMBIA

Administrator for Society's Health Service.—Mr. Hugh G. Buhrman, formerly connected with the American Red Cross, has been appointed administrator for the Mutual Health Service of the Medical Society of the District of Columbia. He will occupy quarters in the society's building. Officers of the service are Drs. Archibald L. Riddick, president; Thomas E. Mattingly, vice president, and Mr. Theodore Wiprud, secretary. The service is under the direction of the board of trustees, consisting of Drs. Henry R. Schreiber, chairman; Harry F. Dowling, Augustus Clagett Gray, William P. Herbst Jr., Kate B. B. Karpeles, Luther H. Reichelderfer and Drs. Riddick and Mattingly.

FLORIDA

Society News.—The Dade County Medical Society was addressed at a recent meeting by Drs. Arthur H. Weiland, Coral Gables, on "Internal Fixation of Transcervical Fractures of the Hip" and Lynn W. Welchel, Miami, "Treatment of Severe Acidosis in Children."—At a meeting of the DeSoto-Hardee-Highlands County Medical Society recently in Wauchula, Dr. Julian L. Hargrove, Bartow, spoke on "Operation for Rupture of Gastric Ulcers."—The Duval County Medical Society was addressed recently by Drs. Turner Z. Cason and Robert H. Cox Jr., Jacksonville, on "Diabetes Mellitus: Analysis of Cases Treated in the Outpatient Department of the Duval County Hospital During the Past Twelve Years."—At a recent meeting of the Leon-Gadsden-Liberty-Wakulla-Jefferson County Medical Society recently in Wakulla Springs, the speakers were Drs. Harold P. McDonald, Atlanta, on "Prostatic Obstruction and Its Treatment"; Albert O. Linch, Atlanta, "Treatment of Ingrowing Toe Nails"; Francis T. Holland, Tallahassee, "Report of Three Cases of Rheumatic Fever," and Edward R. Annis, Tallahassee, "Hypertensions in General Practice."—A recent meeting of the Pinellas County Medical Society was addressed by Dr. Louis B. Mount, St. Petersburg, on "Granuloma Inguinale." Dr. Daniel M. Hoyt, St. Petersburg, addressed the society recently on "Endemic Typhus."—Dr. Exum B. Walker, Atlanta, discussed "Practical Aspects of Common Neurosurgical Problems" before the Polk County Medical Society recently in Lakeland.

GEORGIA

Society News.—Dr. John D. Bradley discussed "Bronchial Asthma with Special Reference to Some of the Newer Drugs" before the Macon Medical Society of Bibb County, Macon, May 16.—At a meeting of the Georgia Medical Society, Savannah, May 9, Dr. Ruskin King read a paper entitled "Abdominal Pain in Children" and Dr. Sherwood C. Lynn reported a case of "Complications of Pneumothorax."—Dr. Columbus H. Barnwell, Chattanooga, Tenn., addressed the Walker-Catoosa-Dade Counties Medical Society May 1 in Ringgold on "The Latest Treatment for Urinary Disease." Dr. David Lloyd Wood, Dalton, also spoke.

Health Program Expanded.—Public health services will be available to all the counties of the state in accordance with a new plan in which the U. S. Public Health Service, U. S. Children's Bureau, the counties of the state and the Georgia Department of Public Health are cooperating. Effective July 1, funds will be provided to the counties through a graduated health budget, allotted proportionately as the size of the county indicates its need for financial aid. The state will be divided into six districts, each to be in charge of a district health unit composed of a medical director, sanitarian, public health nurse and clerk. All health activities in the unorganized counties of under 14,000 population not employing a full time health commissioner will be supervised by the new district unit.

ILLINOIS

Personal.—Dr. Harrison C. Blankmeyer has been appointed superintendent of health of Springfield.—The Community Club of Hampshire sponsored a farewell party June 8 in honor of Dr. and Mrs. Frank A. Olms, who were leaving for Florida. Mrs. Olms was presented with a handbag and Dr. Olms with a watch on which was engraved "From Hampshire Community to Dr. Olms, 1907 to 1939." A check was also presented to the couple.—Dr. John P. Roark, Bushnell, was honored at a combined meeting of the Fulton and McDonough county medical societies recently. Dr. Harold M. Camp, Monmouth, secretary, Illinois State Medical Society, presented Dr. Roark with a medal and a certificate of membership in the fifty year club of the state society.

Chicago

Annual Golf Tournament.—The Chicago Medical Society will hold its annual golf tournament at Olympia Fields Country Club August 2. The many prizes include the Chicago Medical Society Championship Trophy for the lowest gross score; the VanDerslice Trophy, to be awarded to the officer or counselor with the lowest gross score; the Sisson Trophy to be awarded to and to become the permanent possession of the doctor, whether member or officer, with the lowest net score, and the Hospital Championship Trophy, to be awarded to the hospital with the winning hospital foursome. This last prize is being awarded this year for the first time.

Dr. Bailey Goes to University of Illinois.—Dr. Percival Bailey, professor of surgery and neurology, Department of Medicine, Division of Biological Sciences, University of Chicago, has been appointed professor of neurology and neurologic surgery at the University of Illinois College of Medicine. Dr. Hans Brunner, formerly chief of the ear, nose and throat department at the Policlinic of Vienna, has been appointed assistant professor of otolaryngology on a half time basis. Both appointments are effective September 1. These newly created positions are a part of the medical school's expanded program in neuropsychiatry under the direction of Dr. Eric Oldberg, now under way with the construction of a neuropsychiatric institute on the grounds of the Research and Educational Hospital (THE JOURNAL, Aug. 27, 1938, p. 851). Dr. Bailey graduated at Northwestern University Medical School in 1918. He has been professor at the University of Chicago since 1933. Dr. Brunner graduated at the University of Vienna in 1919, later serving on the staffs of the University Clinic of Surgery, Vienna, and the Policlinic of Vienna. During the year 1938-1939 he has been an intern in the Research and Educational Hospital.

MAINE

Personal.—Dr. Ralph S. Belmont, formerly associate medical officer, U. S. Veterans' Administration, West Los Angeles, Calif., has been appointed health officer of the town of Sanford, it is reported.

Society News.—At a meeting of the Washington County Medical Society in Eastport May 25 Dr. Harrison L. Robinson, Bangor, discussed "Epigastric Surgery" and Harold Pressey, Bangor, physical therapy.—The Piscataquis County Medical Society was addressed in Guilford May 25 by Dr. Allan Woodcock, Bangor, on "Fractures of the Femur."—The Portland Medical Club was addressed recently by Dr. Benjamin Zolov on "Sulfapyridine and Sulfanilamide in the Treatment of Pneumonia."

MICHIGAN

Odd Fellows Offer Service as Blood Donors.—Members of the Independent Order of Odd Fellows throughout Michigan are offering their services as volunteer blood donors without charge. The order hopes with the cooperation of the various medical societies in the state to maintain a central list of volunteer donors in each county. According to the *Bulletin* of the Genesee County Medical Society, it is the wish of the order to make its services available whenever required for indigent persons. In the instances in which persons can pay for the service, the money will be used for charitable purposes.

Traffic Safety Training.—The second national institute for traffic safety training will be held at the University of Michigan, Ann Arbor, August 14-26. Sponsoring organizations include the American Automobile Association, American Association of Motor Vehicle Administrators, American Association of State Highway Officials, American Public Works Association, Automotive Safety Foundation, Highway Education Board, Institute of Traffic Engineers, International Association of Chiefs of Police, National Safety Council, Northwestern University Traffic Institute and Yale University Bureau for Street Traffic Research. Further information may be obtained from Sidney J. Williams, 20 North Wacker Drive, Chicago.

Postgraduate Instruction.—Two periods of postgraduate training for practitioners will be available at Receiving Hospital, Detroit, September 17-November 11 and November 12-February 3, under the auspices of the Wayne County Medical Society, Wayne University College of Medicine and the staff of the hospital, according to an announcement from the society. Physicians will meet once a week for ward rounds stressing bedside diagnosis and treatment of medical cases. The course aims to give the practitioners in groups of not more than six opportunity to examine and discuss a wide variety of clinical material at the bedside. Dr. Gordon B. Myers, professor of medicine at the university, will direct the program with members of the staffs of the medical school and the hospital participating. There will be no fee.

MINNESOTA

Gold Medal Awarded to Dr. Hart.—The Southern Minnesota Medical Association presented its annual gold medal to Dr. Vernon L. Hart, Minneapolis, for the best scientific exhibit at the Minnesota State Medical Association. Dr. Hart's subject was "Fracture Problems." Dr. Hart is a graduate of the University of Michigan Medical School, Ann Arbor, where he served from 1929 to 1932 as assistant professor of surgery. He has been an instructor at the University of Minnesota Medical School since 1933.

MISSOURI

Physicians Appointed to Boards.—Recent appointments to the state board of health include those of Drs. Charles H. Neilson, St. Louis; Edward Sanborn Smith, Kirksville; George W. Gay, Ironton; John Aull, Kansas City, and William M. West, Monett. Dr. Doyle C. McCraw, Bolivar, has been appointed a member of the board of managers of eleemosynary institutions; Dr. Charles E. Hyndman, St. Louis, a member of the board of nurses' examiners, and Drs. Frederick J. Taussig, St. Louis, and Paul F. Cole, Springfield, members of the state cancer commission.

Society News.—The Six County Medical Society was addressed June 15 in Sikeston by Drs. Carliss M. Stroud on hay fever and Garold V. Stryker, common skin diseases; both speakers are from St. Louis. This society is composed of Dunklin, Butler, Pemiscot, Mississippi, New Madrid and Scott counties, meeting once each year in a different county. There is only one officer of the six county organization, that of secretary, which this year is held by Dr. Lawrence E. Cooper, Cooter. At each meeting of the society the president of the county society which acts as host serves as president and chairman of the assembly.

NEBRASKA

District Meetings.—The Tenth Councilor District Medical Society met in Hastings recently with the following speakers: Drs. Louis R. Nash, Ingleside, on new therapy in pneumonia; Albert F. Tyler, Omaha, high voltage x-ray therapy; Horace W. Shreck, Holdrege, infections of the bladder, and John H. Waterman, Ingleside, play therapy.—Drs. Esley J. Kirk and Joseph A. Weinberg, Omaha, addressed the Sixth Councilor District Medical Society in York recently on "Diagnosis and Management of Nephritis" and "Radical Surgery of the Breast" respectively.

NEW JERSEY

Personal.—Dr. Joseph S. Van Dyke, Palisades Park, was honored at a dinner at the Knickerbocker Country Club June 22 in celebration of his twenty-five years of service as chief of the women's medical service and twenty-nine years on the staff at the Englewood Hospital. The dinner was given by the hospital staff.

Society News.—Dr. Pauline A. Long, New Brunswick, was reelected president of the New Jersey Medical Women's Association at the annual meeting in May. Drs. Grace W. A. Holmes, Elizabeth, and Eva T. Brodtkin, Newark, were elected vice presidents and Dr. Elizabeth B. Ward, Newark, was made secretary.

NEW YORK

Personal.—Dr. Arthur J. Bedell, Albany, recently delivered an address before the Ophthalmological Society of the United Kingdom in London on "Fundus Changes in Diabetes."—Drs. Duane E. Ensign, McGraw, and John E. Leonard, Hartford Mills, were honored by the Cortland County Medical Society at a dinner June 16 at the Cortland Country Club celebrating their completion of fifty years of medical practice. Dr. Ensign began practice in the county in 1888 after graduation from Eclectic Medical Institute, Cincinnati, and Dr. Leonard in 1889 after his graduation from the Long Island Medical College. Dr. Bert R. Parsons, Cortland, was toastmaster at the dinner.—Dr. Gustave A. Fensterer, Garden City, was honored by the Medical Society of the County of Nassau recently by the presentation of a plaque honoring him as a founder and the first president of the society.—Dr. Charles Rich, Yorktown Heights, was honored by friends and patients recently on his completion of fifty years of practice by the presentation of a silver tray.

New York City

County Society Makes X-Ray Study at World's Fair.—The Medical Society of the County of Queens is making x-ray studies of visitors to the World's Fair, using paper films. The films are read by a committee of radiologists and the report is forwarded to the subject's own physician. Any one who cares to register may have the roentgenogram made. The chairman of the society's committee in charge of this project reported May 23 that up to that date 320 plates had been read and in sixty-seven of them abnormalities needing medical attention were found.

Degree in Forensic Medicine.—Dr. Maurice Powers, Regina, Sask., Canada, received the first degree of doctor of medical science in forensic medicine to be awarded by New York University College of Medicine June 7. Dr. Powers graduated from McGill University Faculty of Medicine, Montreal, in 1934 and has been director of the laboratory of the Royal Canadian Mounted Police in Regina since August 1937. He was on leave to complete his course in scientific crime detection and medical aid to crime solution. The department of forensic medicine at New York University was reorganized in 1936 to provide graduate instruction leading to the degree of doctor of medical science.

NORTH CAROLINA

Personal.—Mr. Frank W. Webster, Southern Pines, has been appointed managing director of the North Carolina Tuberculosis Association. He succeeds Dr. Romulus L. Carlton, Winston-Salem, who has been acting managing director since August 1937, when the late Dr. Louis B. McBrayer resigned because of ill health. Mr. Webster, a graduate of the University of North Carolina, has been superintendent of schools in Southern Pines. He will maintain the offices of the association in Winston-Salem.—Dr. Herman F. Easom, Raleigh,

has resigned as director of the division of industrial hygiene of the state board of health after three and a half years in the position. He will return to the staff of the North Carolina Sanatorium for the Treatment of Tuberculosis, where he was formerly located.—Dr. Carl V. Reynolds, Raleigh, has been reappointed state health officer for another four year term. He was first appointed acting health officer in November 1934 on the death of Dr. James M. Parrott and received the regular appointment in May 1935.—Dr. Charles W. Armstrong, Salisbury, was honored at a testimonial dinner May 16 marking his twentieth anniversary as health officer of Rowan County.

OHIO

University News.—The John and Mary R. Markle Foundation, New York, has made a grant of \$4,100 to Western Reserve University School of Medicine to be used by Dr. Carl J. Wiggers, professor of physiology, to study the nature of ventricular fibrillation and means of sensitizing and desensitizing the heart.

Professor Retires.—Dr. John J. Thomas, associate clinical professor of obstetrics, Western Reserve University School of Medicine, Cleveland, retired at the end of the school year June 14, it is reported. Dr. Thomas graduated from Western Reserve in 1893 and has been a member of the faculty for forty-three years. He will continue in private practice and on the staff of St. Ann's Hospital.

Bureau of Public Education Established.—By action of the house of delegates at the annual meeting of the Ohio State Medical Association in May, a bureau of public education has been established in the executive offices of the association in Columbus. Mr. Richard A. Aszling, a graduate of Oberlin College and recently a member of the staff of the Dayton *Daily News*, has been chosen as director of the bureau.

Society News.—Dr. Charles G. Johnston, Detroit, addressed the Wood County Medical Society, Bowling Green, June 15, on "Long Tube Drainage in the Treatment of Intestinal Obstruction."—Dayton physicians addressed the Hempstead Academy of Medicine of Scioto County in Portsmouth June 5 as follows: Drs. Robert C. Austin on "The Breast"; Edgar L. Braunlin, "Radical Removal of the Breast," and Roy S. Binkley, "Solution of the Indigent Relief Situation in Dayton by the Montgomery County Medical Society."—Dr. Hubert C. King, Lakewood, addressed the Lorain County Medical Society, Elyria, June 13 on "Diagnostic Problems in Coronary Heart Disease and Coronary Occlusion."

PENNSYLVANIA

Hospital News.—Gov. Arthur H. James broke ground recently for two new buildings at Eagleville Sanatorium for Consumptives, Eagleville. The sanatorium is supported by state appropriations, funds raised by public subscription and by private funds. The new buildings will replace four obsolete structures built when the institution was founded thirty years ago.

Meeting of Negro Physicians.—The Pennsylvania State Medical, Dental and Pharmaceutical Association, organized in 1921 by Negro practitioners, met in Harrisburg June 30. The program was devoted to cancer, syphilis and tuberculosis, with the following speakers, among others: Drs. John J. Shaw, state secretary of health; Charles S. Everhart, Harrisburg, chief of the division of syphilis in the state department of health; Stanley P. Reimann, Philadelphia; Henry M. Minton, Philadelphia, and Charles Howard Marcy, Pittsburgh.

Philadelphia

Professor Appointed.—Dr. Howard Canning Taylor Jr., associate professor of obstetrics and gynecology at New York University College of Medicine since 1935, has been appointed William Goodell professor of gynecology at the University of Pennsylvania School of Medicine. Dr. Taylor succeeds the late Dr. Floyd E. Keene. He graduated from Yale University, New Haven, and from Columbia University College of Physicians and Surgeons, New York, in 1924. Recently he has been attending gynecologist at Roosevelt Hospital, associate visiting obstetrician and gynecologist at Bellevue and associate surgeon at Memorial Hospital for the Treatment of Cancer and Allied Diseases. A new building for the department of gynecology and obstetrics is under construction at the university (THE JOURNAL, July 23, 1938, p. 330).

Pittsburgh

Society News.—Dr. Louis E. Phaneuf, Boston, addressed the Pittsburgh Obstetrical and Gynecological Society May 20 on "Management and Results of Operation for Prolapse of the Uterus."

Personal.—Dr. Richard J. Behan was honored with a testimonial dinner by the sisters and staff of St. Joseph's Hospital, Pittsburgh, May 15, in recognition of his twenty-five years of service to the hospital.

VIRGINIA

Dr. Landis Appointed Professor.—Dr. Eugene M. Landis, assistant professor of medicine at the University of Pennsylvania School of Medicine, Philadelphia, has been appointed professor of internal medicine at the University of Virginia Medical Department to succeed the late Dr. James C. Flippin. Dr. Landis took his medical degree at the University of Pennsylvania in 1926 and the degree of doctor of philosophy the following year. He held a Guggenheim Foundation fellowship following his internship and has been a member of the Pennsylvania medical faculty since 1931. He has conducted research in the physiology of the circulation, pathogenesis of edema, peripheral vascular disease and renal disease. In 1936 he received the John Phillips Memorial Medal of the American College of Physicians.

Society News.—Dr. Roy D. McClure, Detroit, addressed the Richmond Academy of Medicine May 9 on "Anoxia and What It Means to the Surgical Patient."—Dr. Robert V. Funsten, Charlottesville, addressed the Lynchburg Academy of Medicine recently on "Low Back Pain."—At the annual meeting of the Virginia Pediatric Society in Charlottesville in May speakers included Dr. DuPont Guerry III, New York, on "Effect of Vitamin K Concentrate on Prothrombin Time and Clotting Time in the Newly-Born."—Dr. Henry B. Mulholland, Charlottesville, addressed the Rockbridge County Medical Society, Lexington, May 22 on "Acidosis, Alkalosis and Dehydration."

WISCONSIN

Society News.—Dr. Walter P. Blount, Milwaukee, addressed the Ashland-Bayfield-Iron County Medical Society, Ashland, June 10 on "Prevention of Deformity in Children."—Dr. Charles R. Marquardt, Milwaukee, addressed the Columbia-Marquette-Adams County Medical Society, Columbus, June 20 on "Diseases of the Urogenital Tract."—At a meeting of the Green Lake-Waushara County Medical Society in Berlin June 14 the speaker was Dr. John W. Harris, Madison, on obstetric problems.—Drs. John A. Toomey, Cleveland, and David S. Hillis, Chicago, addressed the Medical Society of Milwaukee County recently on "Treatment of Contagious Diseases Featuring Convalescent Serum" and "Routine Circumcision of the Newborn Infant" respectively.—Dr. Max Cutler, Chicago, addressed the Milwaukee Society of Clinical Surgery recently on "Indications, Limitations and Results of Radiation in the Treatment of Cancer" and Dr. Chester C. Schneider, Milwaukee, on "Osteomyelitis."

GENERAL

Editor of Anatomy Journal Appointed.—Dr. George W. Corner, professor of anatomy, University of Rochester School of Medicine and Dentistry, Rochester, N. Y., has been appointed managing editor of the *American Journal of Anatomy* to succeed the late Dr. Charles R. Stockard, New York.

Dietetic Meeting.—At the annual meeting of the American Dietetic Association in Los Angeles August 28-31 the speakers will include: Drs. Albert H. Rowe, Oakland, on "Use of the Elimination Diets in the Diagnosis and Treatment of Food Allergy"; William D. Sansum, Santa Barbara, "The Treatment of Diabetes Mellitus," and Herbert M. Evans, Berkeley, "Vitamin E in Human Nutrition."

Symposium on Growth.—The editors of the journal *Growth* announce a symposium on growth and development to be held at North Truro, Mass., August 7-11. Subjects to be discussed are: cell division and differentiation, genes and development, chemical factors, regeneration and organization, and concept of the organism. Among the speakers listed are: Dr. Warren H. Lewis, Baltimore; Paul W. Gregory, Sc.D., Davis, Calif.; Curt Stern, Ph.D., Rochester, N. Y., and Edmund W. Sinnott, Ph.D., New York.

Industrial Hygiene Society.—At the third annual American Conference on Occupational Diseases and Industrial Hygiene, held in conjunction with the meeting of the American

Association of Industrial Physicians and Surgeons in Cleveland in June, a permanent organization was formed, the American Industrial Hygiene Association. William P. Yant, research director of the Mine Safety Appliances Company, Pittsburgh, was elected president; Warren A. Cook, Zurich General Accident and Liability Insurance Company, Chicago, president-elect, and Gordon C. Harrold, Ph.D., Detroit, Industrial Hygiene Laboratories, Chrysler Corporation, secretary.

Changes in Status of Licensure.—The California State Board of Medical Examiners announces the following actions taken at its meeting in February:

Dr. Milton F. Novotny, Burlingame, placed on probation for five years with the understanding that he cease practice immediately and not resume practice until Aug. 1, 1939; that he not be permitted to apply for or have a federal narcotic permit or have narcotics in his possession.

Dr. Harvey Smith, Los Angeles, placed on probation for five years with the understanding that he abstain from all alcoholic beverages, for conviction of driving while intoxicated.

Dr. Joseph T. Wrenn, San Francisco, license revoked, provided that if he immediately file a stipulation with the board that he would not aid or abet an unlicensed individual, nor advertise other than by the use of the ordinary business card, said revocation would be set aside and he would be placed on probation for a period of five years; he was charged with aiding and abetting an unlicensed practitioner, namely William Van Buren.

Dr. William H. Young, San Francisco, license revoked on two charges, aiding and abetting and use of a fictitious name in connection with the so-called Samaritan Treatment for Alcoholism, San Francisco branch.

Award for Chemical Research.—Dr. Nathan B. Eddy, research professor of pharmacology, University of Michigan Medical School, Ann Arbor, and Lyndon F. Small, Ph.D., research associate in organic chemistry, University of Virginia, Charlottesville, received the 1938 award of the American Pharmaceutical Manufacturers Association at the annual meeting at Skytop, Pa. This award, presented for the year's most outstanding chemical research, went to Dr. Eddy and Dr. Small in recognition of their work on substitutes for morphine. The research has been conducted under the auspices of the U. S. Public Health Service as part of a study of habit-forming narcotics directed by the committee on narcotic addiction of the National Research Council. The investigations at Michigan and Virginia have been aided by funds from the Rockefeller Foundation. U. S. Commissioner of Narcotics H. J. Anslinger made the presentation of the award.

Special Society Elections.—Dr. David E. Robertson, Toronto, Ont., was named president-elect of the American Orthopedic Association at the annual meeting in Buffalo June 5-8 and Dr. Frank D. Dickson, Kansas City, became president. Dr. Wallace H. Cole, St. Paul, was elected vice president and Dr. Ralph K. Ghormley, Rochester, Minn., was reelected secretary.—Dr. Foster Kennedy, New York, was elected president of the American Neurological Association at the annual meeting in Atlantic City and Drs. Stanley Cobb, Boston, and Henry W. F. Woltman, Rochester, Minn., were elected vice presidents. Drs. Henry Alsop Riley, New York, and Bernard J. Alpers, Philadelphia, were reelected secretary and assistant secretary, respectively.—Dr. Douglas A. Thom, Boston, was elected president of the American Psychopathological Association at the annual meeting in Atlantic City June 6; Drs. George S. Sprague, White Plains, N. Y., and Bernard Glueck, New York, were elected vice presidents and L. Eugene Emerson, Ph.D., Boston, was reelected secretary.

Award of Anna Fuller Prize.—Trustees of the Anna Fuller Fund have announced the first award of the Anna Fuller Memorial Prize of \$7,500 to a group of five scientists at the Research Institute of the Royal Cancer Hospital of London: Dr. Ernest L. Kennaway, director of the institute; James Wilfrid Cook, Colin Leslie Hewett and Izrael Hieger, chemists, and William Valentine Mayneord, physicist. This fund was established in 1931 in the will of Egbert C. Fuller of Branford, Conn., who left a trust fund of \$1,500,000 for alleviation of suffering from disease and especially for the control of cancer, in memory of his wife, who died of cancer in 1918. Mr. Fuller instructed that the prize should be given "to such person or persons as shall at any time, within successive periods of five years each, commencing one year after my death, make a real and outstanding contribution to knowledge on the subject of cause, care, prevention or cure of cancer." The award was made on the recommendation of the President of the American Medical Association, the dean of Johns Hopkins University School of Medicine and the dean of Harvard Medical School. The committee this year was made up of Drs. Irvin Abell, Louisville, Ky., Alan M. Chesney, Baltimore, and Charles Sidney Burwell, Boston.

The Timing of Symptoms

In a lecture to the Medical and Physical Society of St. Thomas's Hospital on "The Timing of Symptoms," Prof. J. A. Ryle said that the subjective phenomena of disease have a value for the physician which, in the course of time, comes to exceed by far the value of objective signs, and that they proclaim physiologic disturbance which may or may not be due to organic disease. Effort pain in the chest (angina pectoris) is now believed to be the expression of oxygen want in the heart muscle. "Symptoms are universally available; they are the voice of nature," said Dr. John Brown. But they present two difficulties: they cannot be measured and they cannot be studied in animals. But one of their attributes—their timing—lends itself to measurement and has high diagnostic value. Professor Ryle discussed the timing of four classic types of pain: angina pectoris, hunger pain, renal colic and intestinal colic.

ANGINA PECTORIS

The angina of effort lasts as a rule from two to five minutes, but the status anginosus of coronary occlusion may last for hours or return in repeated storms for a day or two. In the former the conclusion has been reached, on the basis of Lewis's teaching, that narrowed or inelastic vessels fail to transmit sufficient oxygenated blood on effort. The cessation of effort restores the balance. But in coronary thrombosis the pain continues until local death of the muscle occurs and the collateral circulation brings relief. A pain of intermediate duration is encountered in patients who have had angina pectoris for a long time. Here one is entitled to visualize increased narrowing or rigidity of vessels so that the balance is less quickly restored. Eventually angina may trouble the patient at rest, particularly in the early morning. Is this due to shallow breathing during sleep or to emotion operating through dreams?

HUNGER PAIN

The hunger pain of duodenal ulcer is held to depend on exaggeration of peristalsis of the pyloric antrum when the stomach is empty or approaching emptiness. But it may also be due to other irritative lesions, such as cholecystitis, or more rarely in early pyloric carcinoma and in nervous states. If no food or medicine is taken it may last for an hour or more and when relieved by food the interval to the next pain is usually between two and three hours but in the case of rapidly emptying stomachs may be as short as an hour. The frequency and periodicity of the pain depend on the food habits of the individual. When pyloric stenosis develops the time interval alters; the pain occurs soon after food from the effort of the stomach to overcome the obstruction.

RENAL COLIC

The factors which determine the arrival of a stone at the pelviureteral junction or in the ureter must be numerous. Attacks therefore come "out of the blue" at no special time, except that they are prone to be nocturnal like Heberden's other "spasmodic complaints." The pain is sustained and crescendo, rarely intermittent. The term colic is therefore misleading. On the other hand, intestinal colic recurs rhythmically in spasm—in obstructive cases at intervals of three or four minutes and lasting a few seconds.

The Cancer Problem

Speaking on behalf of the Empire Day Appeal of the British Empire Cancer Campaign, Dr. Walter Elliot, minister of health, said that the rise in the number of deaths from cancer,

progressive for many years and reaching 74,000 in 1937, could not be disregarded. Though this increase could be explained largely but not wholly by the growing average length of life, for cancer attacked the middle aged and the old more than the young, that was small comfort. A concerted attack on the disease was clearly necessary and took the form of the Cancer Act. Many patients did not receive appropriate treatment or did not receive it until cure became impossible. For this there were many reasons. There was a deficiency of centers with facilities for modern treatment. The Cancer Act would remove or lessen many of these difficulties. The new cancer service, which extended facilities for treatment, would provide greater opportunities for clinical research.

Mr. Cecil Rowntree, surgeon to the Cancer Hospital and vice chairman of the campaign, said that there was evidence of progress all along the line. For some months he had been helping to arrange for an International Cancer Congress at New York. He had received a letter from the president of the New York committee, who said "The German delegates are definitely coming to the conference and their subscriptions have been forwarded."

Committee of Research in Preventive Medicine

The Medical Research Council has appointed a committee to advise and assist it in promoting research into problems of preventive medicine. The members include specialists in various branches—clinical medicine, immunology, nutrition and vital statistics—and health officers from different parts of the country, including members of the medical staff of the Ministry of Health. The chairman is Sir W. Wilson Jameson, dean of the London School of Hygiene and Tropical Medicine. Among the members are E. H. Harries, chief medical superintendent, Infectious Hospitals Service, London; A. Bradford Hill, university reader in epidemiology and vital statistics, London School of Hygiene and Tropical Medicine; R. M. F. Picken, professor of preventive medicine, Cardiff, and W. W. C. Topley, professor of bacteriology and immunology, London School of Tropical Medicine and Hygiene. Three years will be the normal period of service on the committee.

BERLIN

(From Our Regular Correspondent)

May 15, 1939.

The New Leader of German Physicians

As previously reported, Dr. Wagner, leader of the physicians of the reich, recently died. Dr. Leonardo Conti has been appointed as his successor with the title "health leader of the reich." Dr. Conti was born in 1900 in Lugano (Italian section of Switzerland) and bears an Italian first name and family name. His mother was well known in Berlin as a midwife and now plays a leading part in directing the midwives. Dr. Conti was co-founder and secretary of the first anti-Semitic club organized in Berlin in postwar days. In 1923 he became an S A follower. In 1927 he joined national socialism and became the first S A physician in Berlin. Later on he was leader of the Berlin district of the national socialist medical association. In the upheaval of 1933 he was assigned to the ministry of the interior. He engaged in lecturing, for example, on the prohibition of vivisection (he was in favor of rendering scientific experimentations on animals more difficult), on the position of the physician in the third reich and so on. Since 1936 he has been in charge of the health department of the city of Berlin. He now takes Dr. Wagner's place. The change of title is to indicate the change in the status of the physician in the new régime. The most important task assigned to the physician by the political party in control is not to cure illnesses and diseases but to "serve by promoting health and preventing disease."

Nonspecific Encephalitis

Prof. Ulrich Fleck recently pointed out, at a meeting of the medical society of Nuremberg, the difficult clinical situation as regards nonspecific inflammations of the brain. Fleck was for many years assistant in the psychiatric clinic of Göttingen and has gathered valuable information in this field, as this clinic gave special attention to these problems and for many years possessed a special division of encephalitis research. Altogether, Fleck was able to observe fourteen patients in the last three years in the psychiatric and nerve clinic of Nuremberg, which he now directs. These patients included not only youthful ones but some as old as 45 years. The symptoms which Professor Fleck reports are in part quite insignificant. They are limited in certain cases to an indication of pyramid formations, but cerebellar and clearly spastic manifestations may set in. Six of the patients showed leukocytosis, five nystagmus, two double images and four very clear changes in the fundus oculi in the sense of a choked disk. The temperature did not indicate any essential heightening. Puncture yielded in part a considerable increase in the cell count, in some cases also a strong increase of albumin content, and showed mastic curves like those of syphilis. Two of the patients died. One showed perivascular infiltrations which in their distribution came close to conforming to Spatz's type of epidemic encephalitis. In the second patient there were found only clear meningeal infiltrations. The other patients improved more or less after a few weeks and in even a shorter time. According to the anatomic observations these disorders cannot be identified with those of the type of encephalitis japonica (*THE JOURNAL*, Sept. 10, 1938, p. 1030). In contrast with the latter the cerebrum and cerebellum were not affected; the white substance was likewise completely free of infiltrations.

Heredity and Race

Discussion on heredity and race has become relatively quiet since the pertinent laws and regulations have been passed and executed with the well known thoroughness. A few new facts are to be reported because they throw a strong light on conditions here:

First, in an essay composed by the director of "Practical Race Politics" in the department of Race and Politics of the national socialist party, he discusses the term "hereditarily undesirable." He states that finally the demands long insisted on by his department have been incorporated into the legislation of the reich. According to these, not only the hereditary condition of health or disease of the individual but also his kin determines the hereditary worthwhileness of the individual. In other words, it includes what is comprehended under the term "hereditarily fit." The governmental department of Race and Politics has always insisted, he went on to say, in the last years that an industrious, decent and capable family of many children should not be regarded as hereditarily unfit because one of the children perhaps suffered from a physical defect or a feeble-minded child was found among well gifted children. On the other hand, it has become clearer in the last years that the terms "hereditarily healthy" and "hereditarily diseased" in the narrow medical sense are by no means identical with the terms "hereditarily desirable" and "hereditarily undesirable." At the utmost from 20 to 25 per cent of the members of asocial large families that threaten the stability of the German people are hereditarily diseased in the meaning of the law. It is precisely the "hereditarily healthy" members of asocial large families that radically menace the German nation. Not only do nearly all growing children in typically asocial large families show defects, but proof can be furnished that heredity is involved. These observations have been confirmed during the last years through experiences in the selection for the "Honor Book for Large Families."

Recent decisions of two higher courts relative to the famous paragraph 218 of the penal laws should prove of interest. This paragraph deals with abortion and is now strictly enforced. These courts expressly stated that paragraph 218 continues to apply to Jewish women, since the "sure order of political life demands it, although the state, because of its present principles governing the growth of population, has no interest in the birth of Jewish children and would even regard it as desirable if the expected child did not see the light of day. However, the free and unregulated permission of abortion cannot be granted persons of Jewish extraction living in Germany, however undesirable the birth of Jewish children might be." All principles of a medical and social nature which require combating abortion, therefore, do not apply in this case, but only party politics.

These discussions, though apparently purely of a legal nature, concern the physician after all, since they rest on a pretended biologic conception of the racial idea. For this reason, in conclusion, a report is made of the joint session of German and Italian lawyers which took place in March of this year in Vienna in pursuance of the "German-Italian cultural pact" and was attended by the leading jurists of both nations. So much importance was attached to this session that reports appeared also in German medical periodicals. The following fundamental principles were authoritatively laid down at this session: National socialism does not proceed by defending the race through the law but by securing and strengthening the blood order of the German people. To accomplish this the following measures are necessary: (1) to bind law to the race idea and to create a jurisprudence based on racial laws; (2) in the establishment and application of law the cultivation of heredity and race must be placed in the center of all measures.

Eye Injuries

Dr. Brüning reported statistically on the cases of eye injuries treated in the last fifteen years at the Klinik für Augenkrankheiten of the University of Berlin. The following conclusions were drawn: The number of patients tends to correspond to economic conditions. The number of those injured during working hours has increased in the last years. Injuries distinctly increase in summer and around the middle of each week. Hourly distribution reveals an increase during the busiest working hours, with slight emphasis on the morning hours. Grouped according to age, the second decade predominates. Eye glasses are not dangerous for the worker or the motorist; not one case of eye injury to a motorist by splinters from his own glasses has been found in fifteen years. This fact is important because the authorities are considering permitting motorists to wear glasses made of safety glass only.

Consultations for Pregnant Women

The new law on midwives made the advising of pregnant women a duty of German midwives. The national organization of midwives has now ordered every midwife to advise all pregnant women who request advice, which must be given whether it can be paid for or not. An average of three consultations is regarded as necessary during the period of pregnancy. Certificates of pregnancy for use before the national socialist bureau of national welfare have to be issued without cost.

Institute of Research for Rural Hygiene

In a farm home, the birthplace of Pettenkofer, in Bavaria, an institute of research for rural hygiene will be set up, with efforts directed to improving the living conditions of peasants. The work of this institute is to comprehend thousands of farms and villages in the upper region of the Danube. The topics studied will include questions of habitation and clothing, recreation and diet.

Medicosocial Problems in New Zealand

The New Zealand government and the medical profession have not yet reached any agreement over the medical provisions of the social security act. It will be remembered that the prime minister, Mr. Savage, soon after the triumphal return of his party from the polls threatened that if members of the profession would not willingly obey the government they would be forced to do so. Later some modifications of the original plan were promised to meet the opposition of the British Medical Association. But there is still no sign of agreement. This is easily understood when it is considered how utterly opposed are the ideas of the two parties. To the socialistic government it is fundamental that the scheme should provide equal service for everybody. But the universal nature of the plan is its chief objection in the view of the medical profession. Because of the extensive economic repercussions involved and their intimate relation to government policy as a whole, it is impossible to appreciate fully the medical situation in New Zealand without considering the country's economic position generally.

New Zealand, during the past three years, has presented the world with an excellent example of an orthodox system fighting economic planning and unorthodox methods of finance. There is every sign and indication that, up to the present at any rate, orthodoxy is still firmly seated in the saddle. In other words, many of the ideals and aspirations which carried the New Zealand labor party on the crest of the wave into safe anchorage had gradually to be jettisoned in order to keep the ship of state on an even keel.

There are three distinct schools of thought in New Zealand today: 1. Those who are prepared to fight unorthodox methods of finance and political economy to the last ditch and with every means at their disposal; this is the element which suffered overwhelming defeat at the last two general elections. 2. Those who, by steering a middle course of compromise, are endeavoring to implement unorthodox economic measures of reform without unduly interfering with orthodox finance; these comprise a certain section of the labor party headed by the leaders of the government. 3. That other section of the party and its supporters—generally referred to as "left wingers"—who are still adhering to the original pledges of the party and insist that the promises made to the electors should be given effect to. There is good reason for believing that the orthodox element—a minority but influential section of the community—is gaining ground and is benefiting by the adverse conditions, which are not only seriously hampering the government but are lowering its prestige in the eyes of its supporters. Although the government has brought in a number of industrial reforms and social improvements, the policy measures that really counted and that formed the backbone of labor's pre-election platform have not yet materialized. At present the government is faced with three serious problems in which the London money lenders, the New Zealand importers and the members of the New Zealand branch of the British Medical Association play an important part.

Even the friends of labor readily admit today that the government's financial difficulties are mainly due to an attempt to implement unorthodox economic and industrial measures without straying from the narrow path of orthodox methods of finance. By means of these reforms the government succeeded in providing employment and raising the standard of living of the masses of the people. At the same time, however, by relying entirely on an unorthodox method of finance

and allowing a large volume of capital to be sent out of the country, it found sterling funds overseas rapidly depleted. With loans amounting to £17,000,000 falling due in London in the near future the government made a desperate effort in the eleventh hour to replenish its London funds by restricting and in many instances totally prohibiting imports. It is hardly necessary to elaborate on the effect such a revolutionary policy had on an important section of the commercial community in a country where manufacturing industries are so poorly developed. Next in importance to the government's financial policy comes the social security legislation, so dear to the prime minister's heart. Here again the realization of a highly humanitarian policy bristles with difficulties. By far the most important part of the social security scheme is the new state medical service, and the attitude of the members of the British Medical Association creates a great deal of heart burning in government circles. The state maternity service, which is really the first instalment of the new medical system created by the social security legislation, was introduced early in May, and only forty doctors out of about 900 answered the call. Such a poor response does not at all augur well for the successful launching of the main scheme.

These few instances are sufficient to indicate the difficulties confronting a government that is earnestly seeking to bring about greater economic security and better social conditions for the masses of the people. In matters that really count the government is fighting a losing battle with orthodoxy: a battle with a powerful system which, during the last century, has broken many governments. The men who hold the purse-strings in London are, in a measure, dictating the future policy of New Zealand. The conversion of the £17,000,000 loan and the depleted coffers of the New Zealand Reserve Bank in London will enable them to drive a hard bargain.

Although it was the main plank in the government's pre-election program, little is heard of monetary reform in New Zealand today. Even the prime minister's oft repeated references to the utilization of the public credit are things of the past. Driven no doubt by *force majeure*, the labor government promises to become as orthodox as any government New Zealand has ever had. It is true that it was instrumental in raising wages, shortening working hours, increasing pensions and reducing unemployment. But from present indications it would hardly be correct to say that it based these benefits on a sound and lasting foundation. Just as the social security scheme lacks the all important cooperation of the medical profession, so the government's industrial and economic planning lacks the all important cooperation of capital, and in neither case has the government shown sufficient courage or foresight to provide a substitute.

There are many supporters of labor who blame the government for the predicament it finds itself in today: for not taking complete control of the monetary system, for not making use of the public credit, for allowing between £10,000,000 and £15,000,000 of capital to leave the country, for not compelling the medical profession to comply with the state medical service, for prohibiting imports and dislocating the import business, for increasing taxation unduly and raising the cost of living and so on—in short, for not keeping the promises made to the electors and not carrying into effect the mandate given it by the people. But few know of the struggle that is going on behind the scenes; the age old fight between a powerful and influential minority endeavoring to maintain the status quo, thereby refusing to recognize change as an inevitable corollary of progressive development, and a less influential majority, "the masses," who, made aware at first hand of the changing needs of a changing society, must continually strive to keep social development apace with material development.

STOCKHOLM

(From a Special Correspondent)

July 1, 1939.

The Organization of Pneumonia Research

Since the discussion in September 1938 before the Swedish Medical Society on the treatment of pneumonia, attempts have been made to coordinate research in order that comparable data may be available in the different Swedish hospitals. At present the chief difficulty arising over a given case of pneumonia is to decide between the conflicting claims of serum on the one hand and some sulfanilamide preparation on the other. Professor Hilding Berglund, of the St. Erik Hospital in Stockholm, has issued a memorandum on the diagnosis and treatment of acute pneumonia. Without wishing to stereotype the diagnosis and treatment he has realized that, if all the Swedish hospitals were to accept more or less identical procedures, it should be possible to settle the conflicting claims of serotherapy and chemotherapy at a comparatively early date. Preliminary to treatment he recommends the conjunctival test and he requires information concerning the patient's liability to such allergic phenomena as hay fever and urticaria. The contraindications for the administration of horse serum are listed, the indications are mentioned, and advice is given concerning measures to be taken to combat a serious fall of blood pressure. From serum treatment Professor Berglund turns to consideration of chemotherapy. When the pneumococci have been typed and all the other bacteriologic and clinical data have been collected, there may yet be grave doubts as to the treatment to choose. Professor Berglund is opposed to a combination of serotherapy and chemotherapy at present and as long as the relative merits of the two procedures are still in doubt. In early cases in which the type of the infecting organism is definitely established he recommends serotherapy. If that is not available, sulfapyridine should be given, four tablets, each of 0.5 Gm. being given at first, the same dose four hours later, and thereafter two tablets every four hours under close observation, the treatment to be continued for not longer than two days. In fulminating type III pneumonia, very large doses of serum should be preferred to sulfapyridine.

Swedish Wells

The revived interest in the water supplies of country districts reflects to some extent the suspicion that the ravages of infantile paralysis during the last few years are connected with water and water courses. Prince Carl, the enterprising head of the Swedish Red Cross Society, has used his influence in focusing attention on the provision of healthful drinking water in rural areas and has encouraged comprehensive expert surveys of wells and springs in different parts of the country. A survey was carried out in 1938, in the county of Kalmar, by Dr. A. Bergstrand, whose report on 400 wells makes disquieting reading. In more than half of them he found inadequate protection from pollution. In only five instances did he find natural springs the water of which was kept comparatively pure by its free circulation. All the other wells were more or less artificial and as many as five different methods of drawing the water from them were practiced. Everywhere deplorable conditions were detected, and it is to be hoped that country dwellers will be made more well conscious by Dr. Bergstrand's disclosures.

The Late Professor Samuel Hybbinette

Early this year one of the most beloved personalities in the Swedish medical world passed away. Samuel Hybbinette was no ordinary man, and his career was in many respects as unorthodox and unexpected as it could possibly have been. Inconspicuous as a student and hospital intern, he completed his postgraduate training abroad. In 1908 he settled in Stockholm without any important hospital appointment. As his sur-

gical practice grew, word went round among his colleagues about his marvelous dexterity as an operator whose minute knowledge of anatomy was, perhaps, the key to the riddle. He was as surprised as any one when he learned in 1921 that he had been chosen to succeed Prof. Gunnar Nyström as chief of one of the surgical services of the Sabbatsberg Hospital in Stockholm. Skepticism as to the truth of printed words, even when found in standard textbooks, may have had an inhibitory influence on his writings, the quantity of which was inversely proportional to their quality. He made important contributions to the treatment of fractures and he devised an operation for recurrent dislocation of the shoulder joint, now known as the Eden-Hybbinette operation. He did much to perfect operations for cleft palate and harelip. His own palate was as delicate and fastidiously discriminating as were his fingers (he came of French Huguenot stock) and he was known to a wide circle of friends as a gourmet, combining science and art most happily in this domain. His voice was wonderful, and he took every opportunity to keep it trained. Hardly a day passed in his busy life without his giving infinite pleasure to those who heard him sing. February 12 he was celebrating in his club the successful debut of his son, a law student, as a singer. The party was coming to an end just after midnight, and Hybbinette was joining with others in a choral tribute to the shades of the departed when he collapsed and died.

Marriages

CHARLES H. STUBENRAUCH JR., Havana, Ill., to Miss Louise Stiegenmeyer of Champaign at Tuscola, June 26.

RAYMOND TAYLOR JENKINS, Fort Bragg, N. C., to Miss Blanche Brickle of Black Mountain, June 10.

FRANCIS ALVA ELLIS to Miss Margaret Cecelia Bautz, both of Baltimore, at Washington, D. C., July 1.

CARL ALDEN SWEATMAN, Columbia, S. C., to Miss Ruby Lee Turner of Winnsboro, June 8.

PAUL JOSEPH KAMINSKI, Chicago, to Miss Dorothy Irene Marlatt of Danville, Ill., in June.

GEORGE V. PAZDRAL, Somerville, Texas, to Miss Lucille Brown at Fort Worth, June 15.

JOSEPH MAY STOWELL, Albany, N. Y., to Miss Jane Grimshaw of Altoona, Pa., June 17.

PAUL C. COLEGROVE, Oberlin, Ohio, to Miss Shirley Fay Burrell at Cleveland, June 16.

JOSEPH EDWARD SEXTON to Miss Loretta Sturdyvin, both of Champaign, Ill., April 19.

TIBOR CZEISLER, Freeport, Ill., to Miss Wanda Murzyn at East Chicago, Ind., in June.

RALPH JUDSON SYKES to Miss Edith Claire Leake, both of Mount Airy, N. C., in June.

EDWARD YOUNG ROSS, Chicago, to Miss Mollie Mildred Luper of Columbus, May 7.

WILLIAM OSCE SELF to Miss Nancy Anderson, both of Ninety-Six, S. C., in June.

JOHN F. KEITHAN to Miss Sara Lavina Deemer, both of Doylestown, Pa., June 10.

THEODORE STUCKART, Dubuque, Iowa, to Miss Edith Thielen of Elkton, S. D., June 14.

WALTER E. CONSTANTINE to Miss Elizabeth Marie Boland, both of Buffalo, June 17.

MARVIN C. MORRIS, Seattle, to Miss Virginia C. Pringle of Muskegon, Mich., July 3.

GORDON VAIL STODDARD to Miss Eva B. Ross, both of East Orange, N. J., May 27.

OLBERT W. TOPP, Charleston, S. C., to Miss Janie McSwain of Greenville, May 13.

HENRY A. SYDOW to Miss Mary Evangeline McGee, both of Omaha, June 6.

ALVIN A. SCHAYE to Miss Henrietta Heftler, both of New York, May 25.

DALE H. DAVIES to Miss Darlene Hansen, both of Omaha, March 25.

Deaths

Walter Drew McCaw ♂ Brigadier General, U. S. Army, retired, Woodstock, N. Y.; Medical College of Virginia, Richmond, 1882; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1884; entered the army as an assistant surgeon in 1884; veteran of the Spanish-American War; received the distinguished service medal for meritorious service during the World War; was on duty in the chief surgeon's office with the American Expeditionary Force, March-October, 1918, and from October, 1918, to July 15, 1919, was chief surgeon in the American Expeditionary Force; chief surgeon, division of the Philippines in 1914 and in 1915 was in command of the Division Hospital at Manila; department surgeon, Southern Department, Fort Sam Houston, Texas, 1916-1917; following service in France was detailed to serve in Washington, D. C., as assistant to the Surgeon General; was retired by operation of law in 1927; at one time was in charge of the library and museum division of the Surgeon General's Office; professor of military hygiene, 1902-1905, professor of military and tropical medicine, 1904-1913, Army Medical School and commandant, 1919-1923; in 1932 was awarded the Silver Star Medal by the United States; received honors from the French, British and Italian governments; honorary member of the Royal Society of Medicine; author of a chapter on "Tropical Surgery" in Keen's Surgery; aged 76; died, July 7.

Robert Verne Day ♂ Los Angeles; University of Southern California College of Medicine, Los Angeles, 1897; member of the House of Delegates of the American Medical Association, 1925-1926; professor of clinical urology at the College of Medical Evangelists; member of the American Urological Association; fellow of the American College of Surgeons; past president of the Western Branch of the American Urological Association, Los Angeles County Medical Association, and the Los Angeles Surgical Society; member of the city board of health, 1903-1904, and city chemist, 1904-1905; served the Los Angeles County Hospital in various capacities; attending urologist to the Cedars of Lebanon Hospital, California Hospital and the White Memorial Hospital; aged 62; died, April 30, of poison self administered.

Laszlo Detre, Washington, D. C.; Magyar Kiralyi Pazmany Petrus Tudomanyegyetem Orvosi Fakultasa, Budapest, Hungary, 1895; member of the Society of American Bacteriologists; special lecturer on allergy, Georgetown University School of Medicine; senior immunologist, division of infectious diseases, U. S. Public Health Service; working independently, he developed a method of detecting syphilis almost identical with the Wassermann test and announced it only two weeks after Wassermann's first publication; aged 64; died, May 26, of tumor of the brain.

Thomas Stewart Blair, Santa Ana, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1889; in 1918 enrolled as a member of the Volunteer Medical Service Corps and served as acting assistant surgeon in the U. S. Public Health Service in the New England states during the influenza epidemic; first chief of the bureau of drug control of the Pennsylvania State Department of Health; for many years on the staff of the Harrisburg (Pa.) Hospital; aged 71; died, April 12.

Elmer Thomas McGaugh, Potter, Ark.; University of Missouri School of Medicine, Columbia, 1899; member of the Missouri State Medical Association; formerly state health commissioner and secretary of the state board of health of Missouri; mayor of Richmond, Mo., 1931-1932; at one time superintendent of the State Hospital, number 1, Fulton, Mo.; aged 66; died, May 5, of acute dilatation of the heart.

John Major Cooley, Kittanning, Pa.; University of the City of New York Medical Department, 1890; member of the House of Delegates of the American Medical Association in 1923; member of the Medical Society of the State of Pennsylvania; past president of the Armstrong County Medical Society; on the staff of the Armstrong County Hospital; aged 73; died, April 21.

George Kissam Meynen ♂ Jamaica, N. Y.; University of the City of New York Medical Department, 1885; fellow of the American College of Surgeons; during the World War served as medical chairman of the local draft board; one of the founders of Jamaica Hospital and its first surgeon; consulting surgeon to the Mary Immaculate Hospital; aged 78; died, April 7.

Lyle Breslau Honeyford, Catskill, N. Y.; Albany (N. Y.) Medical College, 1898; member of the Medical Society of the State of New York; past president of the Greene County Med-

ical Society; formerly member of the board of education; for many years health officer; served during the World War; on the staff of the Memorial Hospital of Greene County; aged 62; died, April 2.

William Clifford McKee ♂ Los Angeles; Johns Hopkins University School of Medicine, Baltimore, 1913; associate clinical professor of obstetrics at the University of Southern California School of Medicine; member of the Pacific Coast Society of Obstetrics and Gynecology; aged 53; on the staff of the Good Samaritan Hospital, where he died, April 21, while visiting patients.

Ernest Llewellyn Bagby ♂ Enid, Okla.; Ensworth Medical College, St. Joseph, Mo., 1898; member of the American Psychiatric Association; medical superintendent of the Northern Oklahoma Hospital; formerly superintendent of the Western Oklahoma State Hospital, Supply; served during the World War; aged 64; died, May 10, of mitral stenosis and myocarditis.

Adelbert David Dye, Helmuth, N. Y.; Hahnemann Medical College and Hospital, Philadelphia, 1905; member of the Medical Society of the State of New York and the American Psychiatric Association; served during the World War; aged 61; died, April 10, of lobar pneumonia and cerebral arteriosclerosis.

Norton George Becker, Kankakee, Ill.; Northwestern University Medical School, Chicago, 1935; member of the Illinois State Medical Society; on the staff of the Kankakee State Hospital; aged 32; died, May 5, in Chicago of subacute endocarditis following a streptococcal infection of the throat.

Alverdi John Simpson ♂ Summerville, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1897; past president of the Jefferson County Medical Society; served during the World War; member of the board of education; aged 70; died, April 9, in the Adrian Hospital, Punxsutawney, of meningitis.

Vincent Gorman Smith ♂ Staten Island, N. Y.; Jefferson Medical College of Philadelphia, 1916; fellow of the American College of Surgeons; served during the World War; on the staffs of the Richmond Borough Hospital, Richmond Memorial Hospital and the Staten Island Hospital; aged 44; died, April 2.

Wilber G. Fish, Ithaca, N. Y.; Cleveland Medical College, 1893; member of the Medical Society of the State of New York; past president and secretary-treasurer of the Tompkins County Medical Society; aged 80; died, April 12, in the Memorial Hospital of prostatitis and nephritis.

Carl Kirby Arnold, Floydada, Texas; Fort Worth School of Medicine, Medical Department of Texas Christian University, 1915; member of the State Medical Association of Texas; served during the World War; aged 48; died, April 30, in a hospital at Plainview.

Joseph B. Carmichael, Duncan, Okla.; University of Georgia Medical Department, Augusta, 1885; member of the Oklahoma State Medical Association; county health officer; on the staff of the Weedn Hospital; aged 74; died April 22, of carcinoma of the prostate.

Parker Benton Stevens, Alstead, N. H.; New York Homeopathic Medical College and Hospital, 1894; formerly president of the school board; on the staff of the Rockingham General Hospital, Bellows Falls, Vt.; aged 70; died, April 19, of coronary thrombosis.

Bransford Louis Adelsberger ♂ Peoria, Ill.; Washington University School of Medicine, St. Louis, 1920; member of the American Urological Association; on the staff of the Methodist Hospital; aged 44; died, May 9, in a hospital at Pekin of a cerebral hemorrhage.

William John Sheehan, Port Chester, N. Y.; Albany (N. Y.) Medical College, 1897; member of the Medical Society of the State of New York; health officer; aged 67; on the staff of the United Hospital, where he died, April 7, of carcinoma of the neck.

William H. Wesley ♂ Pittsburgh; Northwestern University Medical School, Chicago, 1903; formerly instructor in pharmacy at the University of Pittsburgh School of Medicine; on the staff of the Pittsburgh Hospital; aged 63; died, April 5, of pneumonia.

Robert James Grossman, Butler, Pa.; Western Reserve University Medical Department, Cleveland, 1886; member of the Medical Society of the State of Pennsylvania; on the staff of the Butler County Memorial Hospital; aged 80; died, April 22.

Daniel Edward Osborne, St. Helena, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; for many years a member of the county board of health; aged 82; died, April 3, in the Victory Hospital, Napa.

Marcus Junger ☉ New York; Uniwersytet Jagielloński Wydział Lekarski, Cracow, Austria-Hungary, 1899; aged 63; died, April 28, in the Mount Sinai Hospital, of Welch bacterial infection following an operation for kidney stone.

George Diehl Stahley, Gettysburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1875; for many years professor of biology at the Gettysburg College; aged 88; died, April 16, of cerebral embolism.

James E. Hollingsworth, Strang, Okla.; Barnes Medical College, St. Louis, 1902; member of the Oklahoma State Medical Association; aged 68; died April 3, in the Cottage Hospital, Prior, of atrophic cirrhosis of the liver.

George A. Ribenack, Holcombe, Wis.; Rush Medical College, Chicago, 1891; aged 76; died, April 24, in St. Joseph's Hospital, Chippewa Falls, of coronary artery disease, hypertrophy of the prostate and chronic nephritis.

Henry Middleton Fisher, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1875; member of the Medical Society of the State of Pennsylvania; aged 87; died, April 27, of pneumonia.

Edward Jacob Gangloff ☉ Philadelphia; Temple University School of Medicine, Philadelphia, 1918; for many years police surgeon; aged 46; died, April 4, in the Northeastern Hospital of pneumonia.

Henry F. Becker, Danville, Ill.; Missouri Medical College, St. Louis, 1882; member of the Illinois State Medical Society; aged 80; died, May 1, in St. Elizabeth's Hospital of sclerosis of the cerebral vessels.

Edward B. Beeson, Chicago; Hahnemann Medical College and Hospital, Chicago, 1870; aged 91; died, April 11, in the Albert Merritt Billings Hospital of adenoma of the prostate with obstruction.

Anthony Michael Lisena, Jersey City, N. J.; New York Medical College and Flower Hospital, New York, 1936; aged 29; died, April 29, in the Christ Hospital of acute bacterial endocarditis.

Henry Lawrence Fobes, Auburn, Iowa; State University of Iowa College of Medicine, Iowa City, 1897; member of the Iowa State Medical Society; aged 70; died, April 4, of cerebral embolism.

James M. McManus, Menard, Ill.; St. Louis College of Physicians and Surgeons, 1899; managing officer of the Illinois Security Hospital; aged 62; died, April 11, of diabetes mellitus.

Walter C. Beard, Lewisburg, W. Va.; Vanderbilt University School of Medicine, Nashville, Tenn., 1882; aged 80; died, May 27, of hypostatic pneumonia and cerebral arteriosclerosis.

Josephine Z. Walton, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1901; aged 64; died, April 1, at sea off the coast of South Africa while on a world cruise.

Harry Joseph Frein ☉ Belleville, Ill.; St. Louis University School of Medicine, 1908; on the staff of St. Elizabeth's Hospital; aged 55; died, April 16, of biliary cirrhosis of the liver.

Alfred Herbert Barker, Brooklyn, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1893; aged 79; died, April 25, in Des Moines of carcinoma of the liver.

Everett R. Ulrich, Marine, Ill.; Jenner Medical College, Chicago, 1901; member of the Illinois State Medical Society; aged 60; died, April 11, of acute nephritis following influenza.

Newton H. Barnart, Penns Grove, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1888; bank president; aged 71; died, May 30, of a self-inflicted bullet wound.

James Harry Wilson Anderson, Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1906; served during the World War; aged 70; died, April 8, in Greenville, Pa.

Stanley Mountjoy Hall, Moberly, Mo.; Washington University School of Medicine, St. Louis, 1912; aged 53; was found dead, April 18, probably of coronary thrombosis.

John Ballard Tower, Homestead, Fla.; Northwestern University Medical School, Chicago, 1901; member of the Florida Medical Association; aged 65; died, April 13.

William Conyngton, St. Petersburg, Fla.; Columbian University Medical Department, Washington, D. C., 1902; aged 81; died, April 21, of carcinoma of the bladder.

James A. Bates ☉ Camden, Mich.; Medical College of Indiana, Indianapolis, 1892; aged 72; died, May 17, in the University Hospital, Ann Arbor, of meningitis.

Henry Thomas Hodges, Augusta, Ga.; Atlanta Medical College, 1890; aged 79; died, April 7, in the University Hospital of prostatic hypertrophy with obstruction.

George H. Matchette, McPherson, Kan.; American Medical College, St. Louis, 1878; member of the Kansas Medical Society; aged 84; died, April 30, of senility.

Harry Marshall Heald, Buckfield, Maine; Medical School of Maine, Portland, 1897; aged 68; died, April 24, in Lewiston of coronary thrombosis and arteriosclerosis.

Lewis G. Wetterau ☉ McAdoo, Pa.; Medico-Chirurgical College of Philadelphia, 1898; formerly school director; aged 72; died, April 8, of coronary thrombosis.

Philip Gibson Wickens ☉ Rochester, N. Y.; University of Rochester School of Medicine, 1929; aged 35; died, April 12, in New York of gastric hemorrhage.

Henry Herbert Elliott, The Pas, Man., Canada; Queen's University Faculty of Medicine, Kingston, Ont., 1898; aged 66; died, April 24, of chronic myocarditis.

Michael Aloysius Murray ☉ Wilkes-Barre, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; aged 71; died, April 3.

George Herman Burfield, St. Paul; Northwestern University Medical School, Chicago, 1905; aged 60; died, April 6, of coronary sclerosis.

Thomas A. Cohoe, Pilot Mound, Man., Canada; Manitoba Medical College, Winnipeg, 1905; aged 60; died, April 21, of coronary thrombosis.

Charles L. Aldrich, Paris, Maine; Baltimore Medical College, 1901; aged 75; died, April 28, of cerebral hemorrhage and angina pectoris.

Ernest Jackson Hudspeth, Ruleville, Miss.; University of Nashville (Tenn.) Medical Department, 1906; aged 56; died, April 21, of uremia.

Elgin Dorland Vandervoort, Deseronto, Ont., Canada; University of Toronto Faculty of Medicine, 1881; aged 86; died, March 6.

W. J. M. Covington, College Grove, Tenn.; University of Nashville Medical Department, 1876; aged 84; died, April 27, of myocarditis.

Alexis Dupont Smith, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1882; aged 80; died, April 11.

William H. James, Cleveland; Cleveland Homeopathic Medical College, 1898; aged 63; died, April 6, of chronic myocarditis.

Nona Smith Gould, New York; New York Medical College and Hospital for Women, New York, 1915; died, March 15.

Cynthia Agnes McMahan Jones, Lafayette, Ind.; Woman's Medical College, Chicago, 1879; aged 89; died, April 21, of senility.

Frank E. Bullock, Forest City, Mo.; St. Joseph Hospital Medical College, 1881; aged 80; died, April 15, of coronary occlusion.

Gustave A. Lawrence, Milledgeville, Ga.; University of Georgia Medical Department, Augusta, 1892; aged 75; died, April 7.

Colonel Garrad Ellison, Williamsburg, Ky.; Louisville Medical Department, 1885; at one time mayor; aged 77; died, April 9.

Charles Baldwin Langford, Blenheim, Ont., Canada; Victoria University Medical Department, 1888; aged 71; died, April 1.

Lot Bowen Meadows, Normantown, W. Va.; Baltimore University School of Medicine, 1892; aged 73; died, April 22.

Andrew William Dwyre, Perth, Ont., Canada; Queen's University Faculty of Medicine, Kingston, 1885; died, April 27.

Frederick Melzer, Milwaukee; Milwaukee Medical College, 1906; aged 68; died, April 10, of carcinoma of the lung.

Charles E. Novak, Humboldt, Neb.; Rush Medical College, Chicago, 1903; aged 59; died, April 25, of heart disease.

A. R. Williams, Aiken, S. C.; Baltimore Medical College, 1892; aged 68; died, March 14, of coronary thrombosis.

J. C. Sumner, Hazard, Ky.; Louisville (Ky.) Medical School, 1893; aged 71; died, April 8, of pneumonia.

John Murray Eaton, Toronto, Ont., Canada; Trinity Medical College, Toronto, 1888; aged 81; died, April 8.

Theophilus H. Gamblin, Monticello, Ky.; Louisville (Ky.) Medical College, 1890; aged 72; died, April 1.

Frederick H. England, Los Angeles; Chicago Physio-Medical College, 1896; aged 83; died, April 8.

MISBRANDED "PATENT MEDICINES"
Abstracts of Notices of Judgment Issued by the Food
and Drug Administration of the United States
Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Bick's Vapor Salve.—Bick Co., St. Louis. Composition: Essentially small amounts of menthol, camphor, eucalyptol and carbolic acid, in a petrolatum base. Fraudulently represented as an effective treatment for sore throat, catarrh, tonsillitis, bronchitis, rheumatic pains, eczema, etc.—[N. J. 29044; December 1938.]

Boro-Septol Tablets.—Boro-Septol Chemical Co., Dallas. Composition: Essentially salt, boric acid and sulfocarbols of zinc and copper. Not antiseptic when used as directed; fraudulently represented as a remedy for chronic ulcerated conditions, nasal troubles, leukorrhea, cystitis, etc.—[N. J. 29038; December 1938.]

Cherokee Iron Tonic.—National Medicine Co., Nashville, Tenn. Composition: Essentially small proportions of compounds of iron, quinine and phosphoric acid, extracts of plant drugs including bloodroot, with glycerin, alcohol and water. Fraudulently represented as a remedy for blood disorders generally and as acting beneficially on the liver and stomach.—[N. J. 28988; November 1938.]

Fisher's Columbine Massage Cream.—George B. Fisher, Denver. Composition: Essentially petroleum oil and perfume. Fraudulently represented as a remedy for developing the bust, removing wrinkles, freckles, eczema, scalp diseases, pneumonia, asthma, etc.—[N. J. 29007; December 1938.]

Fisher's Massage Liniment.—George B. Fisher, Denver. Composition: Essentially alcohol (8.9 per cent by volume), with water and small amounts of ammonium carbonate and iodides. For "developing the breast and chest . . . for cuts . . . relieves pain . . . beats the world to use in childbirth." Fraudulent therapeutic claims.—[N. J. 29007; December 1938.]

Fisher's Purgillitis Pencilitis.—George B. Fisher, Denver. Composition: Essentially water, alcohol, epsom salt and flavoring. For appendicitis, ptomaine poisoning, peritonitis, hay fever, abscesses, female complaints, etc. Fraudulent therapeutic claims.—[N. J. 29007; December 1938.]

Ger-Oil.—Ger-Oil Co., Jonestown, Miss. Composition: Essentially a solution or combination of sulfur in turpentine and a saponifiable fixed oil. Fraudulently represented as a remedy for burns, cuts, sores, rheumatic pains, worms in children, "lost manhood," etc.—[N. J. 29004; December 1938.]

Herman's (Dr. Joseph) Special Blood Purifier.—E. Freithofer Mfg. Co., Pittsburgh. Composition: Essentially small amounts of an iodide, an iodate, sodium carbonate, and extracts of plant materials, dissolved in water. Fraudulently represented as an effective treatment of stomach ulcers, blood poisons, skin diseases, rheumatism, female complaints, diabetes, etc.—[N. J. 29006; December 1938.]

Hi-Test Vaginal Suppositories and Femisan Suppositories.—Respectively labeled Hi-Test Laboratories and Femisan Co., St. Louis. Alleged to be identical products; composition not reported. Falsely represented as vaginal antiseptic.—[N. J. 29012; December 1938.]

I. G. Antiseptic.—Norzel's Beauty Products Mfg. Co., Inc., Syracuse, N. Y. Composition: Essentially water, isopropyl alcohol, glycerin and small amounts of common salt, potassium iodide, sodium carbonate, iodine, form and perfume. Fraudulently represented to prevent and eliminate infections, arrest falling hair, remove dandruff, prevent barber's itch, etc.—[N. J. 29002; December 1938.]

Kalm.—Seabury, Inc., New York. Composition: Tablets consisting essentially of aminopyrine (2½ grains per tablet), antipyrine and caffeine. For headache, neuralgia, muscular and rheumatic pain, colds, etc. Fraudulent therapeutic claims.—[N. J. 29008; December 1938.]

Liberty Castoria.—National Medicine Co., Nashville, Tenn. Composition: Essentially extracts of plant drugs including a laxative drug, with Rochelle salt, baking soda, sugar, alcohol (0.93 per cent by volume) and water, flavored with wintergreen and anise. Fraudulently represented as a remedy for dizziness, stomach and bowel disorders, feverishness, worms, etc.—[N. J. 28988; November 1938.]

Liberty Croup and Pneumonia Salve.—National Medicine Co., Nashville, Tenn. Composition: Essentially small amounts of volatile oils including oil of pine, eucalyptol and menthol, in a petrolatum base. Fraudulent therapeutic claims.—[N. J. 28988; November 1938.]

Liberty Rheumatic Elixir.—National Medicine Co., Nashville, Tenn. Composition: Essentially sodium salicylate, a small amount of sodium benzoate, alcohol (3.2 per cent by volume), sugar and water. Fraudulent therapeutic claims.—[N. J. 28988; November 1938.]

Linoll.—Sutton Laboratories, Inc., Chapel Hill, N. C. Composition: Essentially benzoic and salicylic acids, in an ointment base. Fraudulently represented as a remedy for eczema.—[N. J. 28996; November 1938.]

McDonald's Crystalene.—Crystalene Extracts Co., Baltimore. Composition: Essentially alcohol, sugar, water and extracts of plant drugs including nux vomica, licorice and a laxative plant drug. Fraudulently represented as a remedy for biliousness, dyspepsia, dropsy, diabetes, rheumatism, paralysis, etc.—[N. J. 28995; November 1938.]

McDonald's Crystalene Laxative Pills.—Crystalene Extracts Co., Baltimore. Composition: Essentially an unnamed laxative plant drug. Fraudulent therapeutic claims.—[N. J. 28995; November 1938.]

Myraphen.—Plexo Preparations, Inc., New York. Composition: Small tablets containing aminopyrine (approximately 2 grains each) and caffeine; also, larger tablets containing about 5 grains of aminopyrine, each, and caffeine. For menstrual pains, neuralgia, neuritis, toothache, etc. Fraudulent therapeutic claims.—[N. J. 29013; December 1938.]

Na-Sin-Ol.—Na-Sin-Ol Co., Salina, Kan. Composition: Essentially mineral oil, with small amounts of iodine, carbolic acid and camphor. For sinus troubles, hay fever, catarrh, bronchial asthma, earache, etc. Fraudulent therapeutic claims.—[N. J. 29040; December 1938.]

National Skin Salve.—National Medicine Co., Nashville, Tenn. Composition: Essentially small amounts of volatile oils, betanaphthol, green soap and a balsam, in a petrolatum base. For eczema, ringworm, tetter and parasitic skin infections. Fraudulent therapeutic claims.—[N. J. 28988; November 1938.]

Nonat.—Marie Leiblinger & Co., Altadena, Calif. Composition: Essentially a lead plaster consisting of turpentine, camphor, wax, resin and a lead compound. For carbolic acid burns, splinter wounds, toothache, rheumatism, poison ivy, etc. Fraudulent therapeutic claims.—[N. J. 28998; November 1938.]

Nourse Gall Remedy.—Nourse Oil Co., Kansas City, Mo. Composition: Essentially small amounts of a zinc compound and volatile oils including wintergreen and camphor, in a base of petrolatum and lanolin. For "piles," ulcers, boils, skin diseases, etc. Fraudulent therapeutic claims.—[N. J. 29019; December 1938.]

Pon-Tam-Pon and Glycerant.—Pond Mfg. Co., Rutland, Vt. Composition: Tampons consisting of gelatin capsules containing a jelly composed of glycerated gelatin, boric acid and an iodide; a layer of powder composed of silver nitrate and boric acid, and a bundle of wool fibers; the Glycerant contained glycerite of starch and boric acid. The combination was fraudulently represented as an effective treatment of gonorrhea in women; the Glycerant, when used separately, was fraudulently represented as an effective treatment for inflammation, skin diseases, hemorrhoids, sore gums, etc.—[N. J. 29001; December 1938.]

Q-Loid.—Magay Corporation, New York. Composition: White tablets, 5 grains of aspirin each; yellow tablets, averaging 0.3 grain of sulfur and 0.2 grain of antipyrine, each. Fraudulently represented as a remedy for rheumatic conditions, including arthritis.—[N. J. 29016; December 1938.]

Reilly's (Dr.) Herb Tonic.—Thomas I. Reilly, M.D., Boston. Composition: Essentially alcohol, water, extracts of plant drugs including a laxative, and a trace of oil of peppermint. For purifying the blood, destroying systemic germs and poisons, regulating liver and bowels, etc. Fraudulent therapeutic claims.—[N. J. 29005; December 1938.]

Reso-Quinon Vaginal Jelly.—White Cross Pharmacals, Inc., Detroit. Composition: Essentially water, glycerin, a gum, boric acid, with small amounts of resorcinol, oxyquinoline sulfate and lactic acid. Fraudulently represented as a remedy for various female disorders.—[N. J. 29030; December 1938.]

Sanisalva Salve.—Carnation Co., St. Louis. Composition: Essentially small amounts of menthol, oil of sassafras, camphor and carbolic acid, in a petrolatum base. Fraudulently represented as an antiseptic for cuts, burns, skin diseases, catarrh, etc.—[N. J. 29041; December 1938.]

Sunshine Vitamin D Bath Flakes.—Frank J. Peterson, St. Paul. Composition: Essentially a sodium soap containing no therapeutic quantity of vitamin D. Fraudulently represented as a remedy for aches, pains, itching skin, pimples, rheumatism, "athlete's foot," vitamin D deficiency in the system, etc.—[N. J. 29015; December 1938.]

Tree of Life Tonic.—Tree of Life Tonic Co., New Orleans. Composition: Essentially water, alcohol and small amounts of salicylates, oil of peppermint and extracts of plant drugs including a laxative. Fraudulently represented as a remedy for stomach, blood, liver and kidney disorders, diabetes, etc.—[N. J. 29022; December 1938.]

Vallum.—Clematis Laboratories, Waltham, Mass. Composition: Tablets consisting essentially of calcium sulfide, with a red sugar coating. Fraudulently represented as a remedy for varicose veins, varicose ulcers and hemorrhoids.—[N. J. 28992; November 1938.]

Vitawine.—Vitawine Co., Miami, Fla. Composition: Essentially water, alcohol (9.8 per cent by volume), citrates, an iron compound, manganese, and a small amount of vitamin B₁. Fraudulently represented as a remedy for colitis, anemia, neuritis, malnutrition, etc.—[N. J. 29027; December 1938.]

Correspondence

ANGINA PECTORIS AND CARDIAC INFARCTION FROM TRAUMA

To the Editor:—An article entitled "Angina Pectoris and Cardiac Infarction from Trauma or Unusual Effort" by Dr. E. P. Boas, published in *THE JOURNAL* May 13, is devoted in large part to the rebuttal of my observation that physical effort is not a factor in precipitating coronary artery occlusion. I have already presented arguments and shall not repeat them; evidence has now been extended to 1,500 cases and will be published elsewhere. My purpose in writing is to correct several beliefs erroneously attributed to me by the author and to point out that some of his conclusions are unwarranted.

The author gives the impression that trauma was excluded as a cause of cardiac damage and symptoms. This is not true; it is universally admitted that trauma can produce contusion of the heart. It is my belief, however, that trauma does not initiate classic coronary occlusion with secondary cardiac infarction clinically, electrocardiographically or pathologically. In the experiments cited by Boas in which the chests of animals were traumatized, postmortem examination showed myocardial and pericardial damage but not coronary artery occlusion.

Another misconception fostered by Dr. Boas is the failure to differentiate between classic coronary occlusion with infarction and cardiac infarction secondary to coronary insufficiency. I did not include the latter in my series, while many of his cases were probably in this group. These two conditions differ clinically and electrocardiographically as well as pathologically, as Büchner has shown, and should be separated completely.

In support of his belief that physical effort may precipitate coronary occlusion, Boas cites thirteen histories of cases observed by him. However, he does not state the incidence of these cases in his entire medical experience of coronary artery occlusion. Being an authority on heart disease and cardiac consultant to the Workmen's Circle, New York, for many years, he has seen hundreds, if not thousands, of patients with coronary artery occlusion among the laboring classes. If effort were a factor in coronary artery occlusion, he should have encountered numerous instances of coronary artery occlusion due to effort and not only twenty-five. Effort is a factor in attacks of angina pectoris, and almost every patient tells of this relationship, but practically never in coronary artery occlusion.

Since Dr. Boas wishes to apply his conclusions to medico-legal cases, he should have omitted the five compensation cases which were among the thirteen he actually cited. The history given by compensation patients is untrustworthy.

The author postulates intimal hemorrhage as the initial mechanism in the formation of coronary artery occlusion and relates it to effort and to a rise in blood pressure. The fallacy of this belief was recently pointed out (Master, A. M.; Dack, Simon, and Jaffe, H. L.: *THE JOURNAL*, April 22, p. 1620). Intimal hemorrhage is a part of the atherosclerotic process and is independent of external influences. It is found in patients who have been bedridden for weeks or months with cancer, heart failure and the like who give no history of exertion.

In the rare cases of coronary occlusion in which the onset of acute symptoms is associated with effort, it is my belief that the occlusion had been forming or had already formed prior to the exertion. Boas admits that the formation of an occlusion may take place over a period of days. However, once the process has been initiated, effort may bring on pain and other symptoms, although it does not alter the atherosclerotic process. The author saw many of his patients weeks or months after the occlusion; it is probable that, had a careful history been taken at the time of the episode, the presence of symptoms would have been elicited prior to the exertion. I could cite case after case in which coronary occlusion presumably was associated with effort but in which it was possible to prove that the occlu-

sion had occurred several days before, although the patient continued to work. Thus, very recently I was called to see a man 60 years of age who had suffered severe pain during the night following sexual intercourse. His physician had made a diagnosis of acute coronary artery occlusion. Actually, the patient had complained of some substernal pain the week before; and an electrocardiogram taken at that time showed evidence of acute coronary artery occlusion with myocardial infarction, which had not been recognized.

In conclusion, it is evident that the problem of the relation of effort to classic coronary artery occlusion with infarction can be settled only by carefully elicited histories in large numbers of cases, as my associates and I have done in 1,500 cases. Only rarely will there be an apparent association. Yet it should be frequent if effort were a factor, since effort is such a common occurrence in the daily lives of all of us. Furthermore, it is essential to differentiate clearly cases of coronary insufficiency with secondary cardiac infarction from cases of classic coronary artery occlusion, with which I am solely concerned.

ARTHUR M. MASTER, M.D., New York.

SENILE OSTEOPOROSIS

To the Editor:—I have read with great interest your leading editorial on "Senile Osteoporosis" in *THE JOURNAL* February 4, page 434.

In 1930 I wrote a paper on this subject (Rosenfeld, Wilhelm: Ueber die Forme fruste der Osteomalacie, *Med. Klin.* 26:421-422 [March 21] 1930). I am happy that other authors have in their own way succeeded in determining this subclinical form of osteomalacia. As therapeutic measures I used chiefly, besides calcium and vitamin D, subcutaneous injections of minimal doses of epinephrine (from 0.05 mg. to 0.1 mg. of epinephrine hydrochloride for each injection), and this remedy proved helpful in my hands. WILHELM ROSENFELD, M.D., Tel-Aviv, Palestine.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SUNTAN OINTMENTS

To the Editor:—Will you be so kind as to give me the name and formula of a recommended preparation for promoting suntan?

Thomas H. Cates, M.D., Tucson, Ariz.

ANSWER.—There are three different types of cosmetic preparations used for exposure of the skin to strong rays of the sun. (a) The so-called suntan cream, which permits a tanning of the skin but presumably is designed to minimize the "burn." Such a cream may contain a wool fat as a base with hydrogenated coconut oil and other ingredients. One proprietary form is composed of beeswax, distilled water, hydrous wool fat, borax, zinc oxide, hydrogenated coconut oil, amber petrolatum, color and perfume. (b) A cream which is presumed to contain a chemical which will remove the actinic rays of the sun. Such preparations usually contain a substance such as disodium naphthol sulfonate as one of the active ingredients. (c) A preparation which stains the skin to produce a tanned appearance. A lotion of such nature generally contains a pigment and sometimes tannic acid as one of its ingredients.

The "promoting" of suntan is a doubtful procedure. There is no officially recommended preparation for such a purpose. The majority of preparations to be used to minimize sunburn depend on the use of substances that are impervious or partially impervious to ultraviolet rays. Many ointments can be used because of the protection rendered by the base or other ingredients. Zinc oxide ointment is quite efficacious, and even boric ointment can be depended on to give some protection. The following formula may be suggested as a safe preparation: calamine 15 Gm., wool fat 10 Gm., petrolatum 40 Gm., rose water to make 100 cc.

FUNGOUS INFECTION OF VAGINA

To the Editor:—Please discuss the best method of treating vaginitis caused by fungous infections, especially thrush.

E. M. Ragsdale, M.D., Columbia, Tenn.

ANSWER.—Nearly all vaginal or vulvar discharge due to mycoses or fungi are produced by yeast or yeastlike organisms. These organisms consist of two parts, mycelia and conidia. The mycelia are long fiberlike structures, which are usually branched. The conidia are buds and usually the size of a pus cell but may vary considerably.

When typical fungous infection occurs the vulva is considerably reddened and congested and part of the surface may have a slight grayish cast due to dyeing of the epidermis. Since in nearly all cases there is considerable itching, the vulva may show excoriations from scratching. The vaginal wall and introitus are usually covered with tenacious, caseous material which resembles thrush in the mouth of newborn babies. In fact, as shown by Plass and Hesselstine, the two organisms are identical. The walls of the vagina are intensely congested.

The diagnosis of mycotic infections is made most simply by making a hanging drop examination or by taking a smear of a small portion of caseous material and staining for the fungi.

The treatment of yeast infections is generally simple. The thorough application to all parts of the vulva and vagina of a 1 to 5 per cent aqueous crystal violet or gentian violet solution nearly always gives spectacular and gratifying relief. This treatment should be carried out every day or every second day for four or five times or until a cure is accomplished. The patient must be warned that the dyes stain the clothing and that sufficient vulvar pads should be worn at all times. Karnaky advocates a solution of 5 per cent gentian violet in 40 per cent ethyl alcohol, and Hesselstine recommends element iodine as found in one-half to one-fourth strength compound solution of iodine or one-fourth to one-fifth strength tincture of iodine (aqueous dilution).

Shelanski and Kern state that moniliasis will respond to treatment with silver picrate as effectively as to gentian violet without the disadvantage of intense staining. With this method the vagina is cleansed with a cotton sponge saturated with a suspension of kaolin in aluminum hydroxide, rinsed with sterile water and dried. The vagina is then painted with a 1 per cent aqueous solution of silver picrate, and 5 Gm. of 1 per cent silver picrate in kaolin is insufflated into the vagina. These treatments are repeated at weekly intervals.

BLOOD DONORS

To the Editor:—I am the chairman of the local chapter of the Red Cross and have been asked about the advisability of establishing a group of certified blood donors here. Under whose auspices are such lists kept up in most communities? It would seem to me to be a hospital function rather than that of the Red Cross. How often must Wassermann tests be done on donors on such a list? The local Y. M. C. A. man receives many requests for blood donors and has many men willing to give blood, but they are not typed. How is this situation usually handled?

Charles F. Walcott, M.D., Cambridge, Mass.

ANSWER.—The answers to most of these questions can be found in the article by Philip Levine and E. M. Katzin (A Survey of Blood Transfusion in America, THE JOURNAL, April 16, 1938, p. 1243). In the United States different institutions employ various sources for their blood donors. Many hospitals have their own lists, usually consisting mainly of employees; others use donors from commercial agencies and still others use donors from their own lists and employ commercial donors as well. In a few cities noncommercial donor agencies are operated by the local board of health or are under the auspices of the county medical society. A number of organizations, such as the American Legion, the police and fire departments and certain utility companies, maintain their own lists of volunteers compiled from their membership, so that if any employee is injured another can act as a blood donor for him. Finally, of course, when volunteer donors are not available and the patient cannot afford to pay for a certified blood donor, friends or relatives of the patient may be examined and act as the blood donor.

Several chapters of the Red Cross, notably in Augusta, Ga., Baltimore, Md., and Paterson, N. J., have organized blood donor services. Apparently, however, no further promotional work is being undertaken in this activity until a careful analysis of those services already organized has been completed. In London, however, the British Red Cross organized a volunteer blood transfusion service in 1921, and a similar transfusion service is operated by the Red Cross in Rotterdam. These Red Cross transfusion services have done excellent work, making possible thousands of transfusions each year which might otherwise be out of the question. Donors in the service are forbidden to

receive any remuneration, and the patient's identity is kept secret from them. In the Netherlands each donor is given a medal bearing the likeness of Dr. Karl Landsteiner, discoverer of the blood groups, as a memento of his service.

With regard to Wassermann tests, the practice in different communities varies, the intervals between examinations varying from one to six months. The best procedure is to have such tests done shortly before the transfusion. Many hospitals perform a test immediately before a transfusion and for this purpose employ some rapid procedure such as the Kahn or Kline test.

Men who wish to volunteer as blood donors must of course have their blood grouped and must also be subjected to a physical examination, including a hemoglobin determination. Naturally, for this work one or more physicians are required, and if none are available to the Y. M. C. A. in your community it would be advisable to consult with the local county medical society.

BLOOD PRESSURE AND OBESE ARM

To the Editor:—Obviously more pressure is required to shut off the circulation in a thick, fat arm than in a thin one. Can you tell me what, approximately would be the difference in systolic pressure in two patients, one 64 inches (163 cm.) tall and weighing 240 pounds (109 Kg.), the other being the same height and weighing 125 pounds (56.7 Kg.)? I mean, of course, the difference due to thickness of the tissues only, with all other conditions the same. I never have happened to see this discussed, though no doubt it has been many times.

B. A. Higgins, M.D., Sylvan Grove, Kan.

ANSWER.—The inquirer probably confuses the systolic pressure with the sphygmomanometer reading. The reading is not greatly distorted by the thickness of the arm if the usual wide (12 cm.) compression cuff is employed. With the broad cuff an error of about 5 per cent arises. Use of a narrow constrictor, however, may introduce an error up to about 40 per cent. The importance of the width of the cuff was first pointed out by von Recklinghausen (*Arch. f. Path. u. Pharmakol.* 46:78, 1901). The narrow band must overcome the oblique tension of the compressed tissue as well as the internal pressure of the vessels or true arterial tension. With a wide cuff this additional resistance exists only at the edge of the cuff and is therefore a much smaller fraction of the total compressive force (Norris, G. W.; Bazett, H. C., and McMillan T. M.: Blood Pressure, Philadelphia, Lea & Febiger, 1927, pp. 85-87).

There are other sources of error in blood pressure determinations that are much more significant. The most common distortion arises from psychic stimulation of the patient. Prolonged constriction of the arm is a frequent source of error in examinations by the inexperienced. Prolonged constriction may be most uncomfortable. This is especially conspicuous with obese persons. Comparisons of readings obtained by rapid cuff inflation and deflation with those observed when constriction is prolonged reveals that continued compression may elevate the tension as much as from 20 to 40 mm. of mercury. Several rapid observations give more accurate readings (Erlanger, J.: *Am. J. Physiol.* 40:82 [March] 1916).

ROCKY MOUNTAIN SPOTTED FEVER

To the Editor:—Kindly advise me whether it is a vaccine or a serum that is used for prophylaxis of the Rocky Mountain spotted fever carried by the wood tick. I would also like to know whether it is advisable to give it to my child before he goes to camp for the summer and how and where I can obtain it.

Clinton S. Herrman, M.D., Philadelphia.

ANSWER.—The material used as a prophylaxis against Rocky Mountain spotted fever is a vaccine. No serum of therapeutic value has yet been developed nor is the vaccine effective as a cure.

Over a period of fifteen years the usefulness of the Spencer-Parker vaccine as a preventive and in the reduction of the fatality rate (some vaccinated persons may suffer from mild attacks) has been established beyond doubt. The duration of the protection conferred varies a great deal with the individual.

The vaccine is prepared only by the United States Public Health Service at its Rocky Mountain Laboratory, Hamilton, Mont. It is expensive to make and a limited supply is kept on hand at this station and at the National Institute of Health, Washington, D. C. Since there are less than 1,000 cases in the United States each year, mass vaccination is not practical. In certain locations in which the disease is endemic vaccination is extensively employed.

The best prophylaxis is to stay away from tick infested areas. A pamphlet describing ways and means of preventing tick bites for those whose occupations necessitate exposure may be secured at Hamilton, Mont., or Washington, D. C. Small quantities of the vaccine are issued to physicians on request.

MENTAL AND PHYSICAL RETARDATION

To the Editor:—A white girl aged 15 has shown slow growth and some mental retardation since the age of 6 years (she is now three years behind in school). The past history reveals a normal birth, with a birth weight of 6 pounds (2,722 Gm.). There was slight jaundice the first few days. The first teeth appeared at about 1 year. She walked and talked at 21 months. The patient had pyelitis at 13 months and again at about 20 months, and to this has been attributed the slow development. She had measles at 3 years and pertussis at 5; otherwise the past history is negative. There is no family history of glandular dyscrasias. An older sister (aged 19) is normally developed physically and mentally. At the age of 6 years, while in Europe, the patient was advised to take thyroid and she has been taking it intermittently ever since. The mother reports that there was considerable improvement in the child's growth and mental attitude, loss of "pot belly" and an improvement in the texture of the skin and hair following thyroid medication. From the age of 8 to 12 the child attended a clinic, where the thyroid was continued. X-ray examinations of the sella turcica were negative. An intelligence test showed a dull normal in 1936. Repeated tests in 1938 showed an intelligence quotient of 90. From Feb. 27 through May 12, 1937, the patient was given sixteen injections of antuitrin-G, a growth promoting principle derived from the anterior pituitary, by another physician, who also prescribed pituitary, pineal and thyroid extracts by mouth. Before injection the height was 50¾ inches (129 cm.), weight 64 pounds (29 Kg.); at termination the height was 51½ inches (131 cm.), weight 67¼ pounds (30.6 Kg.). During the next few months, however, growth was a little more rapid. Jan. 18, 1939, she reached a height of 54 inches (137 cm.). The total gain in height for that year was 3¼ inches (8.26 cm.). When I saw her January 28, the mother's principal concern was absence of any signs of sexual development. The child had not menstruated as yet and there was no pubic or axillary hair. The patient was fairly alert and looked about 10 or 11 years of age. The body is symmetrical. The skin and hair are dry but not coarse. There is absence of pubic and axillary hair. The height is 54 inches, the weight 72½ pounds (32.8 Kg.). The span is 52¾ inches (134 cm.). The heart and lungs are normal; the pulse is 80. The results of laboratory examinations are as follows: 1. X-ray films of the wrists showed normal bone development; the epiphyses of the long bones were not closed. 2. The basal metabolic rate was -7 (with thyroid medication of one-fourth grain three times a day). 3. The blood cholesterol was 268 mg. Kindly advise whether this is a case of hypothyroidism *per se* or whether possibly other glands are involved. Would further use of antuitrin-G be of any value? What is the prognosis as to her ultimate size and sexual development?

M.D., New York.

ANSWER:—The data are inadequate for an accurate diagnosis, particularly those relating to her early development. If the blood cholesterol is correct, the patient is apparently receiving an inadequate dose of thyroid. It would be desirable to give the patient 1 grain (0.065 Gm.) of U. S. P. thyroid daily (from 0.18 to 0.23 per cent iodine) and if improvement is not satisfactory this might be increased to 1½ grains (0.1 Gm.) daily at the end of three months. If after six months the patient has grown but little, stimulating genital development with pituitary gonadotropic factor (300 units per cubic centimeter) in a dose of 1 cc. daily for twenty-one days might be tried, following with other similar courses of treatment after a rest period of twenty-one days. This should be given in addition to the thyroid. Stimulation of sexual development may produce some stimulation of skeletal development. If the patient has primary hypothyroidism, her condition can be relieved as much as it is possible to relieve it by thyroid alone. Failure to show improvement with the proper dose of thyroid means that other factors are involved. Little improvement is to be expected in her mental development beyond that associated with increased experience. On the other hand, considerable skeletal growth may still occur.

TREATMENT OF OSTEOCHONDRITIS DEFORMANS
COXAE JUVENILIS

To the Editor:—What is the most recent information on the medicinal, dietary and other therapeutic measures used in the treatment of Perthes' disease?

E. C. Hanisch, M.D., St. Paul, Neb.

ANSWER:—The condition referred to should be called Legg-Calvé-Perthes' lesion or osteochondritis deformans coxae juvenilis or coxa plana. Osteochondritis of the hip is a self-limited disease. It should be treated by recumbency in bed with abduction traction of the leg for from five to ten days, then the application of a plaster of paris spica and later a brace. Calot manipulates the hip as in cases of congenital dislocation and applies a plaster of paris cast. Phemister, Kidner and others have operated for this condition. Whitman performed his reconstruction operation with success in arrested cases.

General treatment includes reduction of weight if necessary, removal of foci of infection, proper food, good hygiene, viosterol, cod liver oil, calcium, phosphorus and heliotherapy. The indications are relief from weight bearing, relief from the effects of gravity and relief of muscle spasm. The methods of meeting these indications are absolute and prolonged rest in bed; application of leg traction for from five to ten days (straight at first,

abduction later); application of a plaster spica from the toes to the margin of the ribs for from one to two months; use of crutches; construction of block under the shoe of the opposite side, removal of the cast and making of a model for brace (removable plaster, celluloid spica, Taylor traction hip brace, Thomas hip splint, Bradford abduction hip splint), after from two to four months discarding of braces and use of crutches and shoe block only, and maintenance of nutrition of the entire body by massage of every part except the affected hip region. Operation is rarely indicated. Recent reports, especially from Danforth and foreign authorities, indicate that restoration of the form as well as the function can be accomplished by years of non-weight bearing. Danforth concluded that absence of weight bearing is the essential factor. Movement is not, as a rule, detrimental and may possibly be of importance in maintaining the nutrition of the surrounding tissues and possibly of the epiphysis as well. On the theory that the changes in the femoral head and neck in coxa plana were brought about by a disturbance in the circulation of the epiphysis secondary to the inflammatory changes of the soft tissue, and because healing in coxa plana is sometimes associated with deformity and is usually quite prolonged, owing to the residual scarring and poor circulation, Ferguson and Howorth devised an operation for the revascularization of the femoral head. The hip is exposed through a Smith-Petersen incision and the capsule is incised anteriorly. The hip is then inspected and specimens of synovial membrane and capsule are taken. A small window is cut in the cortex of the femoral neck proximally (the bone and periosteum are retained for the laboratory). Through the opening, several holes are drilled with curved awls and curets into the femoral head in various directions. The opening is closed with a bit of muscle to prevent bleeding into the joint. Careful hemostasis and anatomic closure are made, and a snug adhesive strapping and flannel spica are applied. Ferguson and Howorth found that in the active stage drilling of the femoral head for revascularization halted the advance of the process and resulted in earlier and more complete repair. In the reparative stage, when activity has completely subsided, no treatment is usually indicated. In the residual stage, subtrochanteric osteotomy or arthroplasty may be desirable in selected cases. Degenerative arthritis has been a sequel in some cases. The medicinal treatment includes chiefly the glandular extracts which are indicated in certain of the cases: thyroid in some, pituitary in others and ovarian extract in some cases. Roberts advocated the use of mercury and the iodides.

FERTILIZATION OF OVUM WITHOUT SPERMATOZOA

To the Editor:—In the March 20, 1939, issue of *Life*, page 59, showing photographs under the title "Fatherless Bunnies Are Born to Virgin Rabbit," there is a picture of a black rabbit adult from an ovum allegedly fertilized with heat and not with sperm. Do you feel that there has been an error of technic and has this world, which is so rapidly changing, produced another assault on mother nature? What is the true biological opinion here? I do not recall an asexual cycle in multicellular animals.

M.D., Louisiana.

ANSWER:—More than thirty years ago Jacques Loeb demonstrated that eggs of such invertebrates as starfish or sea urchins could be stimulated artificially (without the use of spermatozoa) and that these would develop into swimming larvae quite indistinguishable from normal larvae produced through fertilization of the egg. Bile salts, heat, mechanical agitation, organic acids or hypertonic solutions were all capable of initiating some development in the egg. Certain invertebrates reproduce normally without fertilization, and, in the case of bees, the male always arises from an unfertilized egg whereas eggs that are fertilized by spermatozoa develop into females.

Among the vertebrates various amphibia (frogs, newts) have been successfully developed without normal fertilization; eggs have been stimulated by various means to develop into larvae, and some have metamorphosed. Eggs from which the nucleus has been extirpated have been fertilized with spermatozoa, and larvae arising have passed metamorphosis into the adult type.

Among mammals, Dr. Gregory Pincus of Harvard has reported for the rabbit that eggs removed from the oviducts and mixed with spermatozoa in a dish can be successfully fertilized and returned to the tubes of another rabbit and complete their development and birth within the normal limits of time. It has also been claimed that unfertilized eggs removed from the oviduct can be stimulated to develop to some extent. No scientific account in which claims are made that such artificially stimulated eggs of the rabbit, reintroduced into the oviducts, have gone sufficiently far in development as to produce living young has been seen. Such an attainment, however, seems entirely possible on the basis of the known facts.

POSSIBLE OVARIAN CYST

To the Editor:—A girl, said always to have been healthy and strong, began to menstruate normally at 11; at 13 the abdomen was aspirated and from 7 to 8 quarts of fluid was removed. She was well for a year and then signs and symptoms of the abdominal trouble began and at 15 some one made six attempts to aspirate without obtaining a drop, although signs of fluid were marked and the distress was considerable. Within a week the distention lessened rapidly and she was "normal" for a year. The signs and symptoms then began to recur, and after another year, when she was 17, she was tapped of 4 gallons of a watery appearing fluid that showed no albumin and was microscopically negative. A guinea pig injection was negative. I have thought of tuberculous, peritonitis, portal obstruction (no enlargement of the liver or of the spleen), and ovarian cyst adherent to the anterior part of the abdomen but I can't understand the watery fluid that is reported "negative." After a month, I plan an exploratory laparotomy after she has had a chance to recover her normal balance, but I need your suggestion. The girl is not underweight, is seemingly strong and has only this gradual accumulation, which has caused an increasing pressure for a year. I can't understand why fluid absorbed at 15 with a dry tap, although she did increase the output of urine.

M.D., New Jersey.

ANSWER.—It is difficult to arrive at a definite diagnosis from the history as given. It is probable that the young girl may have a large ovarian cyst which was aspirated successfully the first time. During the second attempt the cyst may have been partially ruptured by the repeated attempts at aspiration and the fluid may have escaped into the peritoneal cavity, where it was slowly absorbed. It was possible to aspirate the cyst successfully again at the most recent attempt, for it had slowly refilled. Serous cystadenomas of the ovary reach fairly large sizes and accumulate fluid slowly. They are benign in character. A laparotomy is justifiable in this case.

FIXATION OF DIAPHRAGM AFTER ACCIDENT

To the Editor:—A man aged 50, a city fireman, suffered injuries in the cervical region in an automobile accident five months ago. X-ray examinations were negative. A short time afterward a pain developed in the left side anteriorly on the lower border of the ribs. Fluoroscopically he shows fixation and elevation of the left leaf of the diaphragm. His heart is rotated to the right. An electrocardiogram shows some myocardial degeneration. Have you reports on similar cases or can you give me any references? May this be due to an injury to the cervical plexus involving the phrenic nerve or is it a congenital condition?

M.D., N. Y.

ANSWER.—It seems improbable that the man is suffering from an injury to the phrenic nerve because he should have had symptoms of diaphragmatic involvement immediately after the accident. In addition, it appears unreasonable to assume that the automobile accident singled out the third and fourth cervical nerves only on one side. This may be a case of congenital diaphragmatic hernia arising from imperfect development of one or both halves of the diaphragm. This condition is most common on the left side.

OPTIC ATROPHY AND LIGATION OF COMMON CAROTID

To the Editor:—A man aged 47, a common laborer, suffered an incised wound of the right cervical region Dec. 7, 1938. About Jan. 9, 1939, a diagnosis of traumatic aneurysm of the right carotid artery was made. On January 19, the patient was operated on and an aneurysmal sac of the internal carotid which communicated with the internal jugular vein was resected. Due to postoperative hemorrhage it was necessary to ligate the common carotid artery. On April 6 the patient was examined by an eye specialist, who found post-papillitic optic atrophy on the right side and optic neuritis on the left side. The blood and spinal fluid examinations show a negative Wassermann reaction. Apparently there are no mental changes. Will you please let me know if you think there is a definite causal relation between the accident and the optic changes.

Pablo G. Curbelo, M.D., San Juan, P. R.

ANSWER.—From the data presented a definite answer to the question cannot be given. One would like to know, for instance, whether the internal jugular vein was also ligated at the time of the resection of the aneurysm and the definite ligation of the common carotid artery. Secondly, it is important to know the patient's visual acuity, which is not mentioned, and also whether there is loss of vision in one or both eyes and, if there is, whether it occurred directly after the operation January 19. In the third place, the condition of the optic fundi is not clearly stated. Is the optic atrophy on the right side primary optic atrophy secondary to choked disk, or the result of a thrombosis of the central artery?

If one may assume that the optic atrophy on the right is due to thrombosis and that loss of vision occurred immediately after the operation, there would be a causal connection between the operation and the loss of vision. It would be assumed in this case that a thrombosis at the site of the operation was transmitted to the central artery of the eye. The diagnosis

would rest on rapid loss of vision plus changes in the arteries of the retina as viewed by the ophthalmoscope. On the other hand, if there was interference of the venous return from the skull due to ligation of the internal jugular vein, bilateral optic atrophy with choked disk might well follow. It would be unusual, however, for one optic nerve to reach a stage of secondary optic atrophy as rapidly as is indicated by the sequence of events.

Finally, primary optic atrophy on the right side with choked disk on the left side is suggestive of pressure on the right optic nerve, usually the result of neoplasm. The syndrome is known as the Foster Kennedy syndrome and is not related, so far as is known, to interruption of circulation in the common carotid artery or the internal jugular vein. Here again pressure of the spinal fluid, if increased, would be a valuable sign, as well as would the amount of protein in the cerebrospinal fluid.

MANIC-DEPRESSIVE PSYCHOSIS AND MENSTRUAL CHANGE

To the Editor:—A married woman aged 26 is the mother of one child aged 4 years. Approximately eight months ago her menses were reduced from four to one day periods and associated with this change was the development of a psychosis, apparently of the manic-depressive type. The peculiar thing about this phenomenon is the fact that the periods of most marked depression invariably come at the exact midmenstrual point and continue for approximately ten to fourteen days, when there is a practically complete remission for another ten to fourteen days. Although this patient has not been seen by a psychiatrist, I am of the opinion that the problem is not one of hysteria. The patient's domestic life is happy and she has no obvious source of worry. Her physical examination and all laboratory procedures are essentially negative. She has a pilonidal cyst. I should appreciate some word as to the frequency of such psychoses coming on in this cyclic fashion, with the onset of ovulation, and such recommendations as you may have for endocrine therapy.

M.D., Illinois.

ANSWER.—It is not mentioned whether the patient is in a manic state or in a depressed phase. In depressed phases one frequently sees changes or alterations in the menstrual periods. The most common alteration is a marked diminution in the quantity of the flow and then a decrease in the duration of the flow. As is well known, manic-depressive psychoses are also called cyclic or circular psychoses. The latter names have no designation of a relationship to the menses or to ovulation. This patient apparently continues to remain involved with periods of apparent improvement. This is a common observation in all cases of manic-depressive insanity. At the present time most investigators feel that the menses have no active relationship as an etiologic factor in manic depressive psychoses. Theelin and its related substances have had some success in cases of depression (involutional).

PETROLATUM AND HIRSUTISM

To the Editor:—I am using plain petrolatum on my face. I have a difficult skin and I find that the old fashioned yellow petrolatum keeps it in better condition than any cold cream. Will it grow hair? Is it in any way harmful?

M.D., California.

ANSWER.—No application to the skin that is known has the capacity either to increase or to retard the growth of hair. There is a commonly mistaken impression that certain creams are conducive to the growth of hair of some women's faces. This probably arises from the fact that many women become more concerned with the creams they use about the time the skin begins to show signs of aging. At this time, too, most women have an increased growth of facial hair. They often conclude, therefore, that the creams on which they have focused their attention gave rise to the concomitant increase of facial hair. Neither petrolatum nor cold cream of themselves will cause growth of hair. In certain types of skin with acne, the use of creams is contraindicated. It is probable that petrolatum also may aggravate some cases of acne already established.

PULMONARY TUBERCULOSIS AND SULFANILAMIDE

To the Editor:—Will you kindly give me information on the use of sulfanilamide in the treatment of pulmonary tuberculosis?

M.D., Oklahoma.

ANSWER.—There are several experimental observations already published (Rich, A. R., and Follis, R. H., Jr.: *Bull. Johns Hopkins Hosp.* 62:77 [Jan.] 1938; Smithburn, K. C.: *Proc. Soc. Exper. Biol. & Med.* 38:574 [May] 1938; Greey, P. H.; Campbell, H. H., and Culley, A. W., *ibid.* 39:22 [Oct.] 1938; Buttle, G. A. H., and Parish, H. J.: *Brit. M. J.* 2:776 [Oct. 15] 1938) which show that intensive treatment with sulfanilamide alters the evolution of experimental tuberculosis

in guinea pigs. It has been the experience of certain observers, however, that the drug is not highly effective in the treatment of moderately advanced or advanced pulmonary tuberculosis. Hence it would seem best at the present time to use the drug only under the most carefully controlled conditions for the treatment of tuberculosis in human beings. It should be understood that the use of the drug for this purpose is in a highly experimental stage.

ARTERIAL OCCLUSION IN ARMS

To the Editor:—A woman aged 52 apparently had occluded brachial and radial arteries on both sides. In 1932 the patient had been observed in the hospital. She then complained of arthritic pains in the hands and back. Pulse and blood pressure readings were noted. In 1937 a note was made in her record that the pulse could be felt only faintly at the wrist and that blood pressure readings could not be obtained over the brachial arteries. Her Wassermann reaction was negative. X-ray examination of the arm showed the outline of the brachial and radial arteries but no calcification. X-ray examination of her chest was negative. Her fundi were not noteworthy. Good pulsation was felt in both dorsalis pedis arteries, and the blood pressure then was about 180. The process was taken to be arteriosclerotic. I would appreciate greatly any references to similar cases that you might be able to give me. I may say that her symptoms in the hands at the present time are coldness, brittleness of the nails and advanced rheumatoid arthritis. Provided the environment is comfortably warm, her hands show a skin temperature of about 31 C. (87.8 F.) and a response of about a degree to immersion of the legs in warm water. A tourniquet causes fair filling of the veins.

M.D., Canada.

ANSWER.—The most likely cause of the arterial occlusion is arteriosclerosis obliterans, although such a condition is comparatively rare in the upper extremities only. The occlusion may be due to localized atheroma at the origins of the subclavian arteries. Calcification of arteries which is visible in a roentgenogram is not always present in arteriosclerosis obliterans. The differential diagnosis should include cervical ribs, the scalenus syndrome, acral scleroderma and embolic arterial occlusion as the result of heart disease. In general, occlusive arterial disease of the upper extremities is much less serious than similar involvement of the lower extremities, and gangrene occurs less often. In the case mentioned, the good response of skin temperature would indicate that the collateral circulation is adequate and that the arterial blood supply of the hands is fairly good.

FOOD BEFORE SWIMMING

To the Editor:—The director of a summer camp asked me whether it would be injurious or dangerous to allow swimmers two graham crackers and a glass of milk from fifteen minutes to half an hour before swimming. Since I did not feel qualified to answer this question, I am writing to you for your opinion.

P. B. Monroe, M.D., Two Harbors, Minn.

ANSWER.—Under the conditions specified there should be no objection to this amount of food one half hour before swimming, provided the subjects are in a good state of health. From a physiologic point of view, however, the margin of safety is unavoidably reduced, so that if there is any tendency to cramps there would be proportionately more danger. In the digestive state the blood that would normally be concentrated in the digestive organs is partly diverted to the muscles when the latter become active in any exercise. However, the diversion is not complete enough to supply the muscles adequately; consequently neither these nor the digestive organs are adequately supplied. Exercise in cool water thus imposes a demand which may result in cramped muscles with attendant dangers. The demand imposed by the small amount of food specified should not, however, be of severe consequence.

BRITTLE, SPLITTING NAILS

To the Editor:—Can you tell me the cause of dryness and splitting of the nails? The case in mind is one in which the nails become dry, develop a ridge and then split at the ends. What is the cause of this condition and the treatment or cure?

M.D., Texas.

ANSWER.—The causes of brittle or reedy nails are manifold. Frequent washing with soap and water or occupations which require prolonged use of soap and water may be at fault. The use of nail polishes and glazes and their removal with such solvents as acetone remove the natural oil from the nails, drying them. Any local irritation of the skin in the vicinity of the nails and nail beds which may reach the nail matrix can distort the nails and change their consistency, making them less flexible. Invasion of the nails by fungi may make them friable and crumbly. Systemic disorders too may cause the nails to be dry and easily split; these include, among others, hypothyroidism, hyperthyroidism and gout. The nails not infrequently become reedy in old age.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, July 22, page 355.

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Sept. 11-13. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. *Written.* Various places throughout the United States, Sept. 9. *Oral.* Part II. Philadelphia, Oct. 14-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written.* Various large cities in the country, Oct. 9. *Applications must be received by the Secretary by Sept. 1.* *Oral.* Philadelphia, Nov. 3-4. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Various sections of the United States, Oct. 16 and Feb. 19. Formal application must be received before Aug. 20 for the Oct. examination and on or before Jan. 1 for the Feb. examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination and review of case histories (Part I) for Group B candidates will be held in various cities of the United States and Canada, Dec. 2. Applications for admission to Group B, Part I, examinations must be on file not later than Oct. 4. General oral and pathological examinations (Part II) for all candidates (Groups A and B) will be conducted in Atlantic City, N. J., June 6-8. Applications for admission to Group A, Part II examinations must be on file not later than March 15. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).*

AMERICAN BOARD OF OPHTHALMOLOGY: *Written.* March 9. Formal application must be received before January 1. *Oral.* Chicago, Oct. 7 and New York, June 10. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Boston, January. *Applications must be filed on or before Nov. 1.* Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: Memphis, Nov. 22-23. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: New York, April 30 and May 1. Kansas City, Mo., preceding the Region III meeting of the American Academy of Pediatrics. Seattle, preceding the Region IV meeting of the American Academy of Pediatrics. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, December. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlanta, Ga., Dec. 9-11. Sec., Dr. Byrl R. Kirklind, 102-110 Second Avenue S.W., Rochester, Minnesota.

AMERICAN BOARD OF SURGERY: *Part I (Written).* Simultaneously in various centers throughout the United States, Oct. 9. *Applications must be received by the Secretary not later than Aug. 15.* Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

Arkansas June Examination

Dr. D. L. Owens, secretary, State Medical Board of the Arkansas Medical Society, reports the written examination held at Little Rock, June 8-9, 1939. The examination covered twelve subjects. An average of 75 per cent was required to pass. Sixty-six candidates were examined, all of whom passed. The following school was represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine.....	(1937)		87.8
90.9, (1938) 84.3, (1939) 82.2, 82.7, 83.3, 84.4, 84.5,			
84.6, 84.8, 84.8, 84.9, 85.3, 85.4, 85.5, 85.8, 86.3, 86.4,			
86.5, 86.6, 86.7, 86.9, 87, 87, 87.2, 87.3, 87.5, 87.6,			
87.8, 87.8, 87.8, 87.9, 87.9, 88, 88.2, 88.3, 88.5, 88.5,			
88.8, 89, 89.1, 89.2, 89.3, 89.3, 89.3, 89.3, 89.3, 89.4,			
89.4, 89.6, 89.9, 90, 90.0, 90.4, 90.5, 90.7, 90.7, 90.8,			
90.8, 90.9, 91, 91.1, 91.2, 91.3, 91.3, 91.8			

Thirteen physicians were licensed by reciprocity and one physician was licensed by endorsement from January 18 through June 8. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Atlanta Medical College, Emory University.....	(1915)		Georgia
Loyola University School of Medicine.....	(1926)		Illinois
Tulane University of Louisiana School of Medicine.....	(1937), (1938)		Louisiana

Book Notices

A Manual of Fractures and Dislocations. By Barbara Bartlett Stimson, A.B., M.D., Med.Sc.D., Associate in Surgery in the College of Physicians and Surgeons, Columbia University, New York City. Fabrikoid. Price, \$2.75. Pp. 214, with 95 illustrations. Philadelphia: Lea & Febiger, 1939.

It is not difficult to pick out the best parts of this manual on fractures and dislocations and praise this maiden effort of the author. The diction is excellent, the printing all that could be asked and the format handy and convenient. In the text the discussions of fractures and dislocations about the elbow are very well covered; one wishes that equal attention and space had been allotted the all important fractures of the neck and shaft of the femur and the frequent injuries to the other bones of the leg. Even for undergraduate purposes these are far too scantily covered, as fractures of these bones occur most frequently and cause the highest percentage of disability and economic loss the country over. The reason for this discrepancy may lie in the author's explanation of her service in a hospital which treats a high proportion of ambulatory victims of fractures. Strangely, the stirrup cast for the leg, now in general use, is not described or illustrated. The illustrations seem amateurish and some quite misleading; in fact, figure 2, doubling later as figure 82, might better have been left out, with its apparent constriction about the popliteal space and lack of the pillow support insisted on as an essential factor by Russell. In the present era of teaching by visual methods, bone displacements in fractures should be copied with exactness, and methods of splinting or traction, which may be shown with clearness by faithful line drawings, should give detailed information to the reader. Too frequently the student recalls the picture much better than the written text. May this small volume add another stone in the arch of fracture treatment.

Brazilian Medical Contributions. Paper. Pp. 181, with illustrations. Rio de Janeiro: Livraria José Olympio—Editora, 1939.

The author reviews the most important practical achievements and research work contributed by Brazilian physicians. Brazilian civilization began with the arrival of Don John VI, king of Portugal, who brought with him scientists from the University of Coimbra in the seventeenth century. The first school of medicine in Brazil was founded in Bahia in 1815. The Bacteriologic Institute of São Paulo began its work in 1890 after the yellow fever epidemic of the previous year. Pasteur of Paris was requested to choose the director, and he named Dantec. Dantec's health, however, was poor in Brazil and he soon returned to Paris, his assistant Dr. Adolpho Lutz succeeding him as director of the institute. Lutz, the author says, conceived the idea long before Finlay that the mosquito was the possible transmitter of yellow fever. Much research has been done at this institute on bubonic plague, cholera, smallpox, dysentery and diphtheria.

The Butantan Institute was founded after the appearance of bubonic plague in 1899 in Santos primarily to prepare antip plague serum. Dr. Vital Brazil, the director, at the time of his appointment was himself recovering from plague. The Santos epidemic was the first outbreak of plague in Brazil. When plague disappeared the institute started a campaign to educate the public on the danger of venomous snakes and to develop a more effective treatment for snake bites. The interest thus created among the farmers is shown by the fact that they sent to the institute in its first five years of existence only 985 snakes and in the period from 1925 to 1936 a total of 50,000. This institute has become a world center for the study of venom and the preparation of serum to combat its effects.

Oswaldo Cruz, who had been in charge of the technical work in the manufacture of antip plague serum at the Butantan Institute, was made director of a new institute of experimental medicine, which within a few years was to be named in his honor. The Oswaldo Cruz Institute has various branches, each under a group of experts; among them are the branches of protozoology, helminthology, hematology, entomology and chemotherapy. The institute manufactures therapeutic products and

maintains a hospital of tropical diseases, a museum of pathology and a library of 70,000 volumes. Dr. Cruz, on account of his campaigns to improve sanitation and to combat epidemics, was a prominent figure in South American medicine; at his death in 1917 Carlos Chagas became director of the institute, holding that position until his death in 1934. The chapter on the activities of the national health department emphasizes the campaign against leprosy. There are nearly 25,000 beds available or proposed for the care of lepers in Brazil. Yellow fever, although present in Brazil as early as 1686, was absent from Rio de Janeiro for many years after Oswaldo Cruz's campaign of sanitation. The federal government then decided to clean northeastern Brazil of yellow fever. The effort was unsuccessful and in 1923 the Rockefeller Foundation began its collaboration. The results at first were promising, but the disease was not completely eradicated and an unexpected outbreak occurred in Rio de Janeiro in 1928. Yellow fever was then found to be much more widespread in Brazil than had been previously recognized. It has been shown to be present in the jungles over enormous areas. The various yellow fever services in the country have been unified under one administration, and a satisfactory method of mass vaccination against yellow fever has been advanced.

Diseases of the Nose and Throat. By Charles J. Imperatori, M.D., F.A.C.S., Professor of Otolaryngology, New York Polyclinic Medical School and Hospital, New York, and Herman J. Burman, M.D., F.A.C.S., Adjunct Professor of Otolaryngology, New York Polyclinic Medical School and Hospital, New York. Second edition. Cloth. Price, \$7. Pp. 726, with 480 illustrations. Philadelphia, Montreal & London: L. B. Lippincott Company, 1939.

Although the first edition of this book appeared in 1935, extensive additions and changes already have become necessary. Discussions of dermoid cysts of the nose, nasal telangiectasia, injuries to the nose, the cytology of nasal secretions, granulocytopenia, burning tongue, tuberculosis of the larynx, and other subjects have been added or extensively modified. The material has been presented in simple form with emphasis on symptoms, diagnosis and treatment. Some loose statements have crept in, such as "estimation of the severity of the luetic infection of the nose and throat can also be made from the intensity of the reaction" (Wassermann test). While not a conventional textbook or reference book, this should be found helpful to those who accompany their reading of the book with practical clinical and surgical experience.

Recollections of Student Life and Later Days. By C. J. Bond, C.M.G., F.R.C.S., F.L.S. A Tribute to the Memory of the late Sir Victor Horsley, F.R.S. Paper. Price, 1s. Pp. 47. London: H. K. Lewis & Co., Ltd., 1939.

The author was closely associated with Sir Victor Horsley in student life and later days. They roomed together for a time and traveled through Italy together. They helped each other in research work, each apparently inspiring the other. Horsley once asked Bond to state in writing his "own conception, not any one else's, of the nature of the soul." During a period of ill health, Horsley sent Bond a letter enclosing a beautifully made trephine about 4 mm. in diameter, suitable for trephining the skull of a frog. On his next vacation Bond, with the help of this instrument, removed both cerebral lobes from a toad. The animal recovered and could still catch worms and flies, but he had lost the instinctive habit of digging himself into loose ground at the approach of winter. The normal toad does this by an outward shoveling movement of the flexed hind legs, by which it lowers itself, tail end first, into the loose ground. Horsley, while surgical registrar at University College Hospital, spent several week ends with Bond at the Bedford Infirmary, and together they worked on a study of the salivary glands in woodpeckers. Once, after working in the wards all day, Horsley suggested to Bond that they spend the night in operating on a corpse in the postmortem room. This was done and they resumed work in the wards the following day. This particular surgical experience, Bond says, was useful as he was approaching the final F.R.C.S. examination. They arranged their sojourn in Italy so that travel from one place to another would be at night in order to save hotel expenses. The author relates experiences in their long association which have not been referred to previously except perhaps incidentally.

BOOK NOTICES

Jour. A. M. A.
July 29, 1939

The Anaerobic Bacteria and Their Activities in Nature and Disease: A Subject Bibliography. By Elizabeth McCoy, Department of Agricultural Bacteriology, University of Wisconsin, Madison, and L. S. McClung, George Williams Hooper Foundation for Medical Research, University of California, San Francisco. Volume I: Chronological Author Index. Volume II: Subject Index. Cloth. Pp. 295; 602. Berkeley: University of California Press, 1939.

This is a bibliography of literature concerning the anaerobic bacteria. The authors have examined, in the original with few exceptions, 10,500 journal articles and other published reports. While they do not claim that this is a complete index of all published articles in the field, reference to any important article not included may be obtained from the bibliographies of the articles listed. The first volume is a chronological author index beginning with the year 1816. The second volume is a subject index, the names of authors appearing under each subsections referring to dairy products, soil, mud, sand, street dust, water, the intestinal tract of man and of animals, internal organs, urogenital system, circulatory system, the eyes, the skin, the muscles, the bone marrow, foods, surgical materials, amputation and the air; (2) - culture methods, with subsections designated as mediums for counting, mediums for spore production, synthetic mediums, single cell isolation methods, dye metabolism, including fermentation of sugars and other products, nitrogen fixation and the products of metabolism, e. g. ethyl, butyl, amyl and isopropyl alcohols, acetone and pigments. Succeeding classifications include the subjects of physiology, serology and disease relations (botulism, tetanus, gangrene, prophylactic and therapeutic use of antitoxin). A large section on classification has numerous subsections. These volumes illustrate the enormous amount of labor involved in preparing a more or less complete bibliography on any medical subject. The material represents about five years of research and reading, during which time, however, only a few months was available to one of the authors for full time work.

Il trattamento delle sindromi parkinsoniane postencefalitiche con le radici di Atropa belladonna. Dal Prof. Dott. Fedele Negro, direttore della Divisione neuropatologica dell'Ospedale S. Giuseppe Cottolengo in Torino. II. Collana monografica di "Schizofrenia." Paper. Price, 15 lire. Pp. 79, with 3 illustrations. Turin: Industrie Tipografico-Editoriali Rinalte, 1938.

This is a monograph on the treatment of the postencephalitic parkinsonian syndrome with the root of atropine (belladonna). The first and second chapters deal with true Parkinson's disease and the parkinsonian syndrome of postencephalitis, the third with the therapy of the postencephalitic parkinsonian syndrome, and the fourth and fifth with the need of treatment and the progressive nature of this affliction. The author believes that hospital management is essential in the first few months of treatment. A detailed plan is given regarding the preparation of the belladonna root. Both Bulgarian and Italian belladonna roots were used. There is a complete bibliography on this form of treatment and, interestingly, all the contributors are from Italy. This monograph is recommended to all neurologists.

You Can't Eat That! A Manual and Recipe Book for Those Who Suffer Either Acutely or Mildly (and Perhaps Unconsciously) from Food Allergy. By Helen Morgan. Foreword by Dr. Walter C. Alvarez. Cloth. Price, \$2.50. Pp. 330. New York: Harcourt, Brace & Company, 1939.

This is another book on food allergy, written especially for the public. In the four short chapters in part I, the author endeavors to answer the questions "What is allergy?" and "What causes allergy?" and to show how allergic conditions are diagnosed and treated. One of the most interesting parts of the book is the preface, by Walter C. Alvarez, in which he shows how to work out problems in food allergy by the use of elimination diets. The chapter on hints in general cookery is a preface to numerous chapters containing recipes and instructions on how to prepare salads, vegetables, meats, desserts, breads, cakes and relishes. Part III opens with a chapter entitled "What's In It?" in which popular food products are listed and their actual content given. There are lists also, for example, of the kinds of crackers which contain no eggs, of sweet cakes which contain no eggs and of cereals, cakes and

crackers which contain no milk. There is a short chapter on "Jokers in Cooked Foods," to show the allergic person what he may eat unexpectedly when he dines out, for chefs have numerous tricks of throwing in a little of this or that to improve the taste of food. Source foods are listed to show into what products they are made. Wheat, corn, rye, rice, oats, buckwheat, orris root, cottonseed and olives, for example, appear in some of the most unexpected dietary concoctions. The final chapter is an index to enable the reader to find quickly the foods listed in the book which are made without any of the common allergens.

The Newer Knowledge of Nutrition. By E. V. McCollum, Ph.D., Sc.D., LL.D., Professor of Biochemistry, School of Hygiene and Public Health, The Johns Hopkins University, Baltimore, Elsa Orent-Kelles, Sc.D., Associate in Biochemistry, School of Hygiene and Public Health, The Johns Hopkins University, and Harry G. Day, Sc.D., Associate in Biochemistry, School of Hygiene and Public Health, The Johns Hopkins University, Fifth edition. Cloth. Price, \$4.50. Pp. 701. New York: Macmillan Company, 1939.

The authors have concisely surveyed the field of nutrition. The present edition has been completely rewritten but the plan of the book is essentially the same. The first two chapters are historical, tracing the development of the modern concepts in nutrition. Then follow chapters on carbohydrates, lipids, proteins, amino acids, calcium, phosphorus and magnesium, sodium, potassium, chlorine, iron, copper and the nutritional anemias. The latter half of the book is largely devoted to discussions of the vitamins. Following full discussions of the better known vitamins is a chapter on other vitamin factors in which appear such terms as factor Y, factor W, factor U, the anti-gizzard erosion factor, the grass juice factor, the chick anti-encephalomalacia factor and lactation factors. These terms, which have not yet percolated strongly into the general literature, indicate that the vitamin factors are more numerous than was suspected and that other discoveries in this field are to be expected. Following the chapters on vitamins are discussions of the dietary properties of foodstuffs, the dietary habits of man and diet in relation to teeth and longevity and several appendixes giving the comparative nutritive value of numerous foods and the distribution of different organs to show the effect on them of specific food deficiencies.

Bergey's Manual of Determinative Bacteriology: A Key for the Identification of Organisms of the Class Schizomycetes. By David H. Bergey, Robert S. Breed, E. G. D. Murray and A. Parker Hitchens. Assisted by R. E. Buchanan et al. Fifth edition. Cloth. Price, \$10. Pp. 1,032. Baltimore: Williams & Wilkins Company, 1939.

There have been numerous attempts to arrange the species of bacteria in natural systems of classification. The first simple system of Müller listed but two genera (*Vibrio* and *Monas*), which included organisms that would today probably be accepted as bacteria. The present manual was first published sixteen years ago. The first edition contained tabulated descriptions of 832 species of bacteria, while the present edition contains descriptions of 1,335 species with a reference to the original place of publication of 5,600 descriptions. The increase in number is due chiefly to the recognition of groups of genera which seem to be related to one another yet distinct from other groups. Nine new generic names are used: *Noguchia*, *Microbacterium*, *Fusobacterium*, *Pasteuria*, *Caulobacter*, *Proactinomyces*, *Malleomyces*, *Veillonella* and *Blastocaulis*. In spite of the extensive rearrangement of genera and the use of nine new generic terms, few new binomials have been formed and no trinomials are used. It is difficult to prepare a satisfactory outline of classification of bacterial genera and species, especially because the material is in itself incomplete. The authors hope that the classification used in this book will be employed generally. They request the cooperation of all interested persons in the further development of this field of bacteriology. Suggestions for using this manual are followed by an interesting and extensive historical survey of classifications of bacteria with emphasis on the ones proposed since 1923. They review the international rules of nomenclature and discuss how bacteria are named and identified. In the main body of the book under the various family names they give in tabulated form the origin of the name of the species, the reference to the first description, and many details regarding morphology, cultural characteristics, source, habitat and diseases, if any, which they may produce.

Studies on Drug Addiction, with Special Reference to Chemical Structure of Opium Derivatives and Allied Synthetic Substances and Their Physiological Action. By Lyndon F. Small, Consultant in Alkaloid Chemistry, U. S. Public Health Service, University of Virginia, Charlottesville, Nathan B. Eddy, Consultant Biologist in Alkaloids, U. S. Public Health Service, University of Michigan, Erich Mosettig, Research Associate in Organic Chemistry, University of Virginia, and C. K. Himmelsbach, Passed Assistant Surgeon, U. S. Public Health Service. Prepared by direction of the Surgeon General. U. S. Treasury Department, Public Health Service. Supplement No. 138 to the Public Health Reports. Cloth. Price, 60 cents. Pp. 143. Washington, D. C.: Supt. of Doc., Government Printing Office, 1938.

The volume presents various studies conducted by the Division of Medical Sciences of the National Research Council. The chemical and pharmacologic studies were done at the Universities of Virginia and Michigan, respectively. The book is divided into three parts. The first section is devoted to some relationships between chemical constitution and pharmacologic action in the morphine series; the second outlines various attempts made to synthesize substances with narcotic and, in particular, analgesic action, and the third reviews clinical studies of drug addiction, with special reference to opium and allied synthetic substances. This is a notable compilation and should prove an aid to persons interested in chemical and pharmacologic investigations.

Die endokrinen Drüsen des Gehirns: Epyphyse und Hypophyse. Ein Blick in ein interessantes Gebiet. Von Dr. med. Paul Niehans, Chirurg F. M. H. der Klinik von Clarend und der Spitäler von Vevey und Montreux (Schweiz). Cloth. Pp. 280. Berne: Medizinischer Verlag Hans Huber, 1938.

This is a review of the laboratory and clinical knowledge concerning the epiphysis and hypophysis, mainly the latter. Twenty-five separate pituitary hormones are accepted and discussed by the author. For each hormone the history, origin, function, deficiency and excess manifestations, clinical conditions in which it is involved and medical and surgical treatment are outlined. Unfortunately the author fails to sift or evaluate the literature reviewed, so that in consequence the book is a collection of fact and fiction which has accumulated for the past hundred years. Many general conclusions and dogmatic statements are made concerning problems and observations which are still unsubstantiated. Much significant laboratory and clinical work concerning the hypophysis is not mentioned. Treating endocrine deficiencies by transplanting animal glands is the recurrent theme. The author's own work in transplantation figures largely in the book, although this method has not had recognition in the literature. There is no bibliography.

The Vaginal Diaphragm: Its Fitting and Use in Contraceptive Technique. By Le Mon Clark, M.S., M.D. Cloth. Price, \$2. Pp. 107, with 53 illustrations. St. Louis: C. V. Mosby Company, 1939.

This brief monograph relates solely to the diaphragm and jelly combination method of contraception, which is extensively used today. The method is fully described and well illustrated, so that the physician who wishes to acquaint himself with the details of the procedure will find the work entirely adequate. There is no attempt on the part of the author to discuss the various methods of birth control or to compare their relative merits. He limits his discussion to the vaginal diaphragm used in combination with a spermicidal jelly and recommends this method to patients who desire such protection.

Orthopedic Appliances: The Principles and Practice of Brace Construction for the Use of Orthopedic Surgeons and Bracemakers. By Henry H. Jordan, M.D. Foreword by E. G. Brackett, M.D. Cloth. Price, \$4. Pp. 412, with 176 illustrations. New York, Toronto & London: Oxford University Press, 1939.

There is no question that this book is timely. There has been an urgent need for a guide to the technic and manufacture of braces as well as to the plaster of paris technic which is necessary in their construction. The author has covered a vast ground and has covered it creditably. However, the most valuable part of the book is the chapter dealing with the plaster of paris and the brace model technic. The principle of construction is particularly well brought out in the description of body corsets, which goes into minute details. What one misses in the book is descriptions of many practical, excellent orthopedic devices used in this country, for instance Funsten's pronation splint for pronation contracture and the spring back brace. On the other hand, the description of the different hinges and par-

ticularly the different types of knee joint locks, with mechanical construction drawings, is very valuable. Splints for the upper extremity are fairly well represented, e.g. abduction, cock-up and different types of finger splints. There is a chapter on the use of x-rays for landmarking and checking up on the construction of braces. On the whole, this is a valuable book, even though it does not quite do justice to the development of the brace technic in this country. It is the only book in the English language that has so far appeared on this subject and is indispensable to the orthopedic surgeon.

Der Rheumatismus: Sammlung von Einzeldarstellungen aus dem Gesamtgebiet der Rheumaerkrankungen. Herausgegeben von Professor Dr. Rudolf Jürgens, Stellv. Direktor der Universitätsklinik für natürliche Heil- und Lebensweisen und Chefarzt des Augusta-Hospitals Berlin. Band XIV: Chirurgie und rheumatische Krankheiten. Von Dozent Dr. A. Fonio, Chefarzt des Bezirkskrankenhauses Langnau (Bern, Schweiz). Band XV: Der Muskelrheumatismus. Von Professor Dr. Max Lange, Krankenhaus Rotes Kreuz, München. Boards. Price, 15 marks; 6 marks. Pp. 235, with 26 illustrations; 84, with 20 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1939.

This contribution to the series of monographs on rheumatism consists principally of a brief description of the various diseases which may affect the joints or which may produce symptoms referable to the joints. Although surgery appears in the title, the only surgical bias seems to be in the citation of a considerable number of articles from surgical journals. One wishing to consult this monograph for suggestions on the surgical treatment of various disorders of the joints would be disappointed.

Prof. Max Lange classifies muscular rheumatism as infectious and noninfectious. After brief discussions of the clinical aspects, he considers the diagnosis and differential diagnosis. The treatment is given in considerable detail and includes, with much excellent advice, some discussions which cannot be considered as representing a scientific approach. The bibliography contains not a single reference outside the German literature.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Osteopathy: "As Taught and Practiced in the Legally Incorporated Colleges of Osteopathy of Good Repute" Construed.—In 1901 the medical practice act of Kansas was amended to authorize the board of medical registration and examination to license persons to practice osteopathy. The amendment specifically prohibited persons so licensed from administering drugs or medicines of any kind and from performing operations in surgery. In 1913 an osteopathic practice act was enacted creating a state board of osteopathic examination and registration, prescribing qualifications to be possessed by applicants for licenses and authorizing the board to issue to a successful applicant "a certificate granting him the right to practice osteopathy in the state of Kansas, as taught and practiced in the legally incorporated colleges of osteopathy of good repute." The defendant, Gleason, obtained a license to practice osteopathy under the act of 1913 and owned and operated a hospital at Larned, Kan. The state, on the relation of the Attorney General, instituted quo warranto proceedings in the Supreme Court of Kansas against Gleason, contending that he was engaged unlawfully in the practice of medicine and surgery and asking the court, in effect, to enjoin him from so practicing.

The petition, among other things, alleged that Gleason, not having a license issued by the board of medical registration and examination, administered medical and surgical treatment to numerous patients in his hospital and that he permitted other osteopaths to render similar treatment in the hospital. Gleason admitted that he had no license issued by the board of medical registration and examination, that he was licensed to practice osteopathy and that he had for many years treated patients both medically and surgically. He contended that his license to practice osteopathy authorized him to engage in the practice of medicine and surgery, including drug therapy, because the

school from which he graduated in 1915, the American School of Osteopathy of Kirksville, Mo., taught then and in 1913 when the osteopathic act was enacted the use of medicine and surgery, including drug therapy, for the treatment and alleviation of human ills. He contended that the osteopathic school or system of healing includes the practice of medicine and surgery and that colleges of osteopathy use the same textbooks on the practice of medicine and surgery as are used in approved schools of medicine generally and devote sufficient time to these subjects to qualify graduates in the use and practice of medicine and surgery. He admitted permitting other osteopaths to practice medicine and surgery in his hospital.

Since the enactment of the osteopathic act in 1913, the Supreme Court said, Kansas has had two boards of examiners, composed of persons having different educational qualifications, issuing different types of certificates. One, the board of medical registration and examination, is composed of members who have received the degree of doctor of medicine from some reputable medical college or university. It is authorized to issue certificates "to practice medicine and surgery." The other, the board of osteopathic registration and examination, is composed of osteopaths, graduates of a reputable school or college of osteopathy. It is authorized to issue certificates "to practice osteopathy." By these separate acts, the court thought, the legislature clearly recognized a distinct difference between the practice of medicine and surgery and the practice of osteopathy. The court pointed out that a certificate authorizing one to practice osteopathy, whether issued prior to 1913 by the board of medical registration and examination or since that time by the board of osteopathic registration and examination never has been recognized by the laws of Kansas, nor by the courts of Kansas, as authorizing its holder to engage in the practice of medicine and surgery. Osteopaths in Kansas are limited to the practice of osteopathy in harmony with the fundamental principles of osteopathy as generally known and understood and as taught in osteopathic schools or colleges of good repute in 1901 and 1913. While osteopaths, the court continued, are expected to continue to study, to make progress, to learn more about their profession and to apply such knowledge in their practice, yet they are still limited to the practice of osteopathy as that science or system was known and understood when the laws under which they were licensed were enacted. If, as suggested by Gleason, osteopathy has abandoned its fundamental opposition to drug therapy and operative surgery, meaning by that term surgery by the use of surgical instruments, and now includes the use of those things in its system of healing, that fact, the court said, never has been recognized by the legislature of Kansas.

The defendant argued that since the osteopathic act required an applicant to be examined in surgery a licentiate was authorized to practice surgery generally, including operative surgery. But, said the court, the word "surgery" as used in the osteopathic act means surgery by manual manipulation. The general use of a knife or other instruments in surgical operations was regarded as unnecessary and opposed to the osteopathic system of treatment. Gleason further pointed out that the prohibition contained in the law of 1901 denying to osteopaths the right to administer drugs or medicine of any kind and the right to perform operations in surgery was omitted in the 1913 act and contended that this omission constituted an authorization for licentiates under the 1913 act to engage in such practice. It seemed clear to the court that the legislature intentionally omitted the prohibition from the 1913 act but that it did not follow that thereby the legislature intended to confer unrestricted authority on osteopaths to administer drugs and perform operations in surgery. Considering the fact that surgery in its primitive and broadest sense, the court said, includes adjustment of bones, muscles, ligaments and nerves by manual operation, and that skill in doing so is taught in osteopathic schools and colleges and occupies a major place in the science or system of osteopathy, the prohibition against osteopaths performing operations in surgery contained in the 1901 act was an inaccurately used expression and should have been omitted from the 1913 act for that reason alone. Furthermore, the system of osteopathy, generally speaking, strongly opposed the use of drugs as remedial agencies in the treatment of the sick, afflicted or injured. Osteopathic schools and colleges of good

repute contained no course for the study of materia medica. There was no real occasion, therefore, to prohibit osteopaths from using drugs, since they made no claim or pretense of doing so, nor did they study to qualify themselves for such use. The legislative intent of the act of 1913 was, the court repeated, to recognize the system of osteopathy as then taught in its schools and colleges of good repute. What was then taught in osteopathic schools was a matter of common knowledge. Their courses of study were available, as were the writings of its founder and other leading osteopathic teachers and practitioners. Osteopathy could be as readily designated by the language used in the act as in any other way. The act was not void for uncertainty in its failure more specifically to define osteopathy nor was it, as construed by the court, void as unconstitutional because it delegated to legally incorporated colleges of osteopathy the right to determine the methods and scope of practice of osteopathy in Kansas. The act, however, did not authorize the state board of osteopathic registration and examination to approve schools or colleges which did not conform their teachings to the fundamental principles of osteopathy.

The medical practice act, in providing that its provisions shall not apply to any registered osteopathic physician, means no more than that one who desires to practice osteopathy is not required to make application to the state board of medical registration and examination and have that board pass on his qualifications and issue to him a certificate to practice osteopathy. It does not mean that none of the provisions of the medical practice act applies to osteopaths, and hence that osteopaths may practice medicine and surgery in all particulars with impunity. Any other construction, the court said, would render ludicrous and nugatory the work of the legislature in treating the practice of medicine and surgery as one thing and the practice of osteopathy as another.

The osteopathic act, the court concluded, did not authorize licentiates to use drugs, in so far as such drugs are given as remedial aids. It did not authorize them to practice in the general field of operative surgery with surgical instruments but limited them to manipulative surgery.

The court, therefore, ousted defendant Gleason from the practice of medicine and surgery. The court declined to oust him from permitting other licensed osteopaths to practice medicine and surgery generally in his hospital. Such an order would, the court pointed out, require the defendant to watch continuously what other licensed osteopaths did in his hospital, and this burden should not be put on the defendant.—*State ex rel. Beck, Atty. Gen. v. Gleason (Kan.)*, 79 P. (2d) 911; 83 P. (2d) 425.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Primary Carcinoma of Liver in a Child: Case Report. D. H. Drummond and J. P. Tollman, Omaha.—p. 361.

Basophilic Aggregations in the Newborn.—Since it is known that the blood of the fetus and the newborn of many animals contains immature cell forms, McCord and Bradley tried to establish percentages of basophilic aggregations at short intervals after birth in order to fix the time at which substantially constant numbers of basophilic aggregations begin to exist. They found that, as in the case of laboratory animals, newborn infants present basophilic aggregations obtained from circulating blood in numbers and percentages in excess of adult, healthy individuals. The maximal basophilic aggregation percentage, which averages 5.3, was present during the first twenty-four hours after birth both in premature and in full term infants. Unlike animals, a diminution to adult percentages took place rapidly, and usually at about the eighth day a normal level was reached. Continuation of testing in premature infants to the end of forty days after birth indicates no substantial rise after normal percentages have been reached. Occasion for the application of the basophilic aggregation test in instances of suspected lead poisoning in young children is not nullified on the assumption that children more than 10 days old may continue to exhibit high percentages of these cells. In young albino rats, high percentages of erythrocytes containing basophilic substance persist until near the hundredth day of life. This fact militates against their use in certain experimental studies, particularly with lead.

Cerebral Vascular Disease and Sickle Cell Anemia.

A clinical and pathologic study of two cases of sickle cell anemia accompanied by symptoms of cerebral vascular disease is reported by Bridgers because of its contribution to the pathogenesis of the disorders of the central nervous system in sickle cell anemia. The two cases show that sickle cell anemia may first become manifest through the appearance of signs and symptoms indicative of cerebral vascular disease. The clinical features in such cases lead to the diagnosis of either cerebral vascular thrombosis or intracranial hemorrhages. The pathologic changes seen in one of the cases establish the fact that in sickle cell anemia the large subarachnoid cerebral arteries may undergo gradual obliteration with final complete closure through the operation of a process identical with that which results in occlusion of the splenic arteries. This process is one of end-arterial intimal proliferation and not of thrombosis. In the second case the necropsy showed that another vascular process, quite different from endarterial intimal proliferation, also occurs in sickle cell anemia. This process develops in connection with the small intracerebral vessels and may result in multiple focal necroses and hemorrhages in the brain, in contrast with the large infarcts that characterize the proliferative obstructive process in the larger arteries. The nature of this second process is not clear.

Physical Fitness of School Children.—Souther and her associates limit their study to the ability of each of four indexes of body build to identify children who are likely to be physically unfit, using as criteria of reference the observations of the physician with respect to the child's general nutritional condition and the child's annual rate of gain in weight. The indexes studied were the Baldwin-Wood height-weight index, the Pryor width-weight index, the nutritional status indexes of Franzen and his co-workers and the arm-chest-hip index. Each index has been set to identify, for the purpose of this study, the lowest 15 per cent of the boys and girls. The 713 boys and girls 7 years of age selected have been defined arbitrarily as the group most likely to be in need of medical care or nutritional assistance. A single pediatrician made two

annual physical examinations of each child. At the same time a single technician took the necessary anthropometric measurements according to the prescribed technics. The children's medical history and their socio-economic status were ascertained, and they were weighed at quarterly intervals during the period of observation (from nineteen to twenty months). The agreement between the physician's clinical judgment and each of the indexes is that the physician who examined these children classified forty of the 348 girls as poorly nourished at 7 years of age. The Baldwin-Wood index identified twenty-five girls, or 63 per cent of these forty, as underweight. When the Pryor width-weight index was applied only 28 per cent of the forty girls were picked out as underweight, and with the arm-chest-hip index the percentage identified as below par was somewhat less (10 per cent). The results of testing the nutritional status indexes show that the weight index identified only 3 per cent, and the indexes for arm girth and subcutaneous tissue picked out 5 per cent of the forty girls. Assuming that the children who exhibited an unsatisfactory percentage gain in weight (those in the lowest 10 per cent of the group) were likely to be in a poor physical condition, the results of the comparison between annual percentage gain in weight, so far as showing the usefulness of any of the four indexes, are even more discouraging. The Baldwin-Wood index showed the maximal agreement (29 per cent), while the nutritional status index for weight failed to identify any of the thirty-five girls whose weight gain was considered unsatisfactory. Similar analyses of the boys indicate that the indexes also failed to identify a large number of the boys whom the physician judged to be poorly nourished or whose weight gain was markedly below average. Since such indexes do not furnish the school health officer with a satisfactory method of identifying a child who may be in need of medical attention or nutritional assistance, the clinical examination must certainly form an integral part of the assessment, especially if determining the need of medical care is to be one of the objectives of a school health program. Until the physician is furnished with more satisfactory and practical tools for evaluating the child's physical fitness, it may be wise to supplement the clinical examination with some simple measure of the child's progress, such as his relative gain in weight. Observations made on the 713 children are being used to investigate this problem.

Serum Treatment of Scarlet Fever.—Top and Young studied the therapeutic effect of scarlet fever convalescent serum, scarlet fever antitoxin and a nonspecific serum during a period of one year. During this time, 995 patients with moderately severe scarlet fever were admitted to the hospital and received a single dose of one of the serums by the intramuscular route. The study was controlled by alternating the administration of the serums. No statistical difference was demonstrated between the serum groups when certain status on admission factors were tested. Convalescent serum and antitoxin exerted a similar therapeutic effect. The value a scarlatinal serum exhibits in the treatment of moderately severe scarlet fever does not appear to be gaged entirely by its antitoxin content. There was about one sixth the value in using nonspecific serum in the treatment of moderately severe scarlet fever as there was in using specific serum.

Acetarson for Congenital Syphilis.—Pillsbury and Perlman have followed 187 children with congenital syphilis who were given acetarson for periods varying from two months to six and one-half years. In eighty-seven of these cases the average period between registration of the patient and the diagnosis of syphilis was three years. The effect of acetarson alone in reversing the Wassermann and the Kahn reaction of the blood has been only moderately satisfactory for infants less than 6 months of age but as good as that of standard preparations, or better, for older children. The incidence of all reactions has been 10.7 per cent; that of serious reactions, particularly nephritis, 4.6 per cent. For newborn infants the use of a system (Bratusch-Marrain) of dosage based on weight is essential; reactions are reduced but not entirely prevented by this means. Nephritic reactions occurring suddenly and insidiously are the greatest single drawback to acetarson therapy. The authors do not believe that administration of the drug should be resumed after such a reaction. In general, the occurrence of gastrointestinal and dermatitic reactions does not contraindicate further acetarson therapy. Acetarson is probably not administered as directed to patients treated at home, as the incidence of reactions among patients treated under controlled hospital conditions was four times that observed among outpatients. Among the eighty-seven children observed for more than three years after acetarson therapy, one serologic relapse occurred. No instance of clinical relapse of a lesion not present when treatment was started has been observed. There were twenty-two clinical relapses among the eighty-seven children who were under medical observation for an average of three years before antisyphilitic treatment was given. The responsibility of the parent or guardian is one of the most important features of treating congenital syphilis with acetarson by mouth, and lack of cooperation by the parent is a sufficient contraindication to acetarson therapy. The effect of acetarson in arresting congenital syphilis is inferior to that of arsphenamine and bismuth preparations. The performance of a routine Wassermann test of the blood and of a precipitation test are absolutely essential to an adequate pediatric examination.

Cryotherapy for Acne and Its Scars.—Karp and his associates treated fifty cases of acne or postacne scars with a mixture of solid carbon dioxide, acetone and precipitated sulfur. The acetone serves a triple function: it dissolves the sebum, it seems to increase the speed with which the solid carbon dioxide changes to the gaseous state with consequent further lowering of the temperature and it produces a more uniform paste. Applications are repeated at weekly intervals. The mixture causes superficial refrigeration with subsequent exfoliation. This exfoliation is the result of an inflammatory process, with varying amounts of edema. The therapeutic response is due to the repeated exfoliations. The term cryotherapy is

applied to this treatment. Forty-seven of the fifty patients were apparently either cured or greatly improved. Two patients failed to respond and one suffered a recurrence. Thirty-three were cured or greatly improved within four months. The other fourteen were equally benefited but required more than four months of treatment. Patients who had been cured by roentgen therapy showed further cosmetic improvement when cryotherapy was used solely with the aim of rendering the postacne scars and pits less conspicuous. Cryotherapy should be guardedly administered when there is atrophy of the skin even when a history of roentgen irradiation cannot be elicited from the patient. Perhaps more important than radiodermatitis is the presence of a melanotic nevus within the affected area or in its immediate vicinity. More than a superficial inflammatory reaction should not be set up. Exfoliation should not be repeated until the inflammation of the preceding treatment has subsided. The authors report the cures with considerable reservation, because no case has been observed for a sufficient length of time to warrant considering the cure permanent.

Carcinoma of the Lip.—Newell reviews 390 cases of carcinoma of the lip that were observed at the Johns Hopkins Hospital from 1900 to 1933. The diagnosis of carcinoma was made in every instance from sections, except in ten of the earlier cases (all cases of hopeless cancer). The lesions were generally well advanced. Besides affecting the percentage of five year cures unfavorably, delay in treatment shows the need for more prompt attention to lesions of the lip. The proportion of patients who showed metastasis or recurrence on first examination (36.4 per cent, or 143 of 390 patients) indicates the seriousness of delay in diagnosis and treatment. The average duration of symptoms was in excess of two years. The lesion first noticed by most of the patients was a small, painless ulcer, which at first grew slowly. Scabs often formed, and the lesion sometimes healed before a raw area reappeared. Frequently the patients stated that they had had fever blisters before but that this time the fever blister did not heal. The lesions usually became worse after the use of salves and mild caustics, although there was seldom any associated pain. Other early lesions noticed by the patients were warts, cracks, fissures, leukoplakia and chapping of the lips. There were 344 cases of squamous cell carcinoma, forty-four cases of basal cell carcinoma and two cases of adenocarcinoma. Only 2 per cent of the basal cell lesions occurred on the lower lip, and none of the adenocarcinomas. "Malignant wart" is a term used to indicate the papillary, squamous cell, low grade type of carcinoma. Clinically a lesion cannot always be diagnosed as benign or malignant. Emphasis is put on the microscopic study in relation to prognosis and therapy. Follow-ups were obtained in 328 of the 390 cases. The percentage of five year cures for the entire series was 61.6. The incidence of metastasis or recurrence on first examination was 36.4 per cent. Of 176 patients with no clinical evidence of metastases in whom local excision alone was performed there were 80.9 per cent with

five year cures. The percentage of five year cures was 85.3 in those cases in which local excision plus dissection of the cervical glands was carried out but no metastasis found microscopically. Of eighty-three cases in which both local excision and cervical gland dissection were done but in which metastasis was found, the percentage of five year cures was 22.5. The operative mortality was 3.7 per cent in 349 cases; twelve deaths occurred in the last two groups of patients.

Section of Spinothalamic Tract.—In doing forty-one chordotomies during the last three years, Hyndman and Van Epps saw reason to question the accepted location of the spinothalamic tract as well as the accepted disposition of its fibers. They report six cases in which the operation was done with the patient under local anesthesia only. Sections were made in the cord according to various patterns, and cutaneous sensibility was tested at the operating table. Their conclusions are that the spinothalamic tract mediating the sensations of pain and temperature extends from a point about midway from the dentate ligament to the anterior roots to a point about midway from the anterior roots to the anterior median fissure. Hence a complete section should include this region. The region extending 2 mm. anterior to the dentate ligament contains no fibers conducting sensations of pain or temperature. As one progresses from the lower segments of the body upward, the corresponding "pain fibers" are disposed more and more anteriorly in the cord. It is possible, therefore, by differential section to eliminate the sensations of pain and temperature in the chest and to retain these modalities in the lower extremities.

Androgen for Male Climacteric and Gonadal Insufficiency.—Dunn treated fifteen cases of gonadal insufficiency with testosterone propionate. There were five cases of eunuchoidism, two of testicular hypoplasia, two of testicular atrophy following mumps, two secondary to anterior pituitary deficiency (one with infantilism and one with cryptorchidism) and four of the climacteric. The results of the treatment showed, in general, a relief of symptoms proportionate to the dosage administered. The treatment was effective in relieving the nervous and mental symptoms associated with the hypogonadal syndrome. The dosage required varied with the degree of gonadal

deficiency; from 30 to 150 mg. weekly, administered hypodermically, gave the best results. As the therapy is one of replacement, symptoms may recur when the deficiency state recurs. Percutaneous application of testosterone propionate in hydrous wool fat shows evidence of effective absorption of the male hormone by the manifestations of increased hirsuties and a general constitutional effect. Its present strength does not appear adequate to relieve the symptom state. The increase in physical energy, as well as the ability to sustain physical effort over a greater period of time, was marked. There was a greater mental ability not only in concentration but in the fulfilling of social and economic responsibilities. There is, first, a mental quietude and repose replacing the previous irritability and, later, as the energies improve, there is increased interest in business and social activities. When neurocirculatory symptoms are present, their abatement contributes materially to the mental and physical improvement. It is not always possible to obtain rapid therapeutic effects, even by hypodermic administration of the testosterone propionate. Accordingly, the author believes that proper sedation has a field of application during the early acute clinical conditions, but as soon as a sufficient amount of the compound has been given the sedation should be reduced and later discontinued.

Clinical Use of Synthetic Male Sex Hormone.—Turner used synthetic male sex hormone, testosterone propionate, in the treatment of fifty-four patients (from 7 to 70 years of age) with various types of genital anomalies and dysfunctions, which included adult hypogonadism, sexual diminution associated with senescence, adiposogenitalism, gynecomastia and benign prostatic hypertrophy. In doses of from 10 to 75 mg. weekly the hormone was found effective in every hypogonad case, as evidenced by promoting hair and penile growth, producing erections and emissions, developing the libido and potentia coeundi and by generalized changes in secondary sex characteristics. Gynecomastia with normal secondary sex development is apparently not influenced by injections of the hormone. The androgen brought about considerable relief of the subjective symptoms of sexual diminution associated with senescence, and in cases of benign prostatic hypertrophy, as shown by the clinical improvement in the usual symptoms and signs of prostatic obstruction. No untoward by-effects occurred in any of the cases treated.

Adrenal Cortex Extract for Addison's Disease.—During the last three and a half years Thompson and his associates observed the effect of the prolonged administration of adrenal cortex extract in seven patients with marked Addison's disease, varying in age from 18 to 49 years. All of them showed the typical clinical signs of the disease, including pigmentation, reduction in blood pressure and characteristic chemical alterations in the blood. In two patients active tuberculosis was present. Of the seven patients, four are now living and three are dead. It would appear that with adequate doses of extract patients may be maintained in a sufficiently satisfactory condition to carry on normal activity, provided no active tuberculous infection is present. The smallest dose that has ever accomplished this purpose is 10 cc. daily by the subcutaneous route, and usually much more is required. The addition of sodium salts does not improve the condition of the patient if

an adequate amount of extract is administered. The authors believe that their patients would all probably have been in better health if they had been able to administer three or four times as much extract as they did. The failure of the pigmentation to disappear completely and the tendency of the concentration of total base in serum to remain at or just below the lower level of normal appear to confirm this point of view and suggest that with the doses that they were able to administer they had only partially controlled the deficiency. Their experience convinces them that with sufficiently large doses of extract many patients with Addison's disease may be kept completely well. Every patient with Addison's disease should be under constant observation of a physician in order that emergencies may be treated as soon as they arise. Only in this way can unnecessary deaths be avoided. Patients should be instructed to begin sodium salts and cortical extract in large doses at the first sign of an impending crisis. Infections of all types should be avoided and every infection that does occur should be regarded as an emergency. In a crisis it is important to begin treatment at once, as delay may be fatal, to administer intravenously 10 cc. of an active adrenal cortex extract and about 170 cc. of a 5 per cent solution of dextrose in physiologic solution of sodium chloride every hour, until vomiting stops and appetite returns. There is no danger at present of giving an overdose of extract. Early in a crisis a patient may be revived by extract alone. The maintenance dose of the extract (at least 10 cc. daily) should be increased during an infection. If no active tuberculosis is present, patients may be maintained in a satisfactory condition for long periods. There appears to be some relationship between the nutritional state of the patient and the level of the blood pressure. When the basal metabolism is low, raising it to normal with a suitable dose of thyroid is an important part of the treatment. Under such circumstances no aggravation of the disease has been observed from its use. There appears to be a relationship between the function of the ovary and the adrenal cortex.

Adrenal Cortical Hormone for Addison's Disease.—In the treatment of six cases of Addison's disease, Thorn and his collaborators implanted subcutaneously pellets of crystalline desoxycorticosterone acetate. None of these patients could be maintained in good condition by means of sodium chloride therapy alone. Sodium chloride therapy was continued in five of the six cases, as it has been shown that it greatly reduces the necessary dose of desoxycorticosterone acetate. A diet of constant mineral intake was provided. The daily maintenance dose of desoxycorticosterone acetate in sesame oil, injected once daily, was determined. The maintenance of optimal body weight, normal blood pressure, normal plasma volume, positive sodium and chloride balance and normal concentration of plasma electrolytes was regarded as evidence of adequate treatment. Daily injections of the hormone in oil were then discontinued and, under local anesthesia, pellets of crystalline desoxycorticosterone acetate, weighing from 50 to 150 mg. each, were inserted subcutaneously in the infrascapular region. The implantation of

pellets occasioned no untoward reaction. Striking and continued improvement followed the implantation in all the cases. The changes were similar to those previously observed following a daily injection of the hormone in oil. In one case in which the dextrose tolerance curve was abnormal, continued treatment with pellet implants was associated with a marked change toward normal. Pellets of synthetic hormone are slowly absorbed and thus exert a prolonged effect. Implantation of the pellets obviates the necessity for the daily injection of the hormone and, in addition, effects a great economy of the hormone. Pellets weighing from 50 to 150 mg. are absorbed at a rate of from 0.25 to 0.35 mg. a day. It is desirable to insert pellets of a standard size of from 125 to 150 mg., obtaining varying concentrations of hormone by increasing or decreasing the number of pellets rather than by varying the size. The maintenance of a rather constant rate of absorption as a pellet decreases in size is probably accounted for by either a softening of the pellet, which would result in more rapid absorption, or canalization, which would offer a greater surface for absorption. The fact that a prolonged period exists during which absorption is so constant greatly favors the practical applicability of this technic.

Immunity to Vaccine Virus.—Rivers and his colleagues studied a large group of children in order to obtain more complete information concerning the amount and duration of immunity produced by cultured vaccine virus against the New York City calf lymph strain of virus. In addition, the immunity produced by cultured virus against other strains of calf lymph vaccine virus and the differences that the manner of performing primary inoculations with cultured virus have on subsequent immunity are considered. The 331 children who had received one inoculation of cultured virus resulting in a primary take from one month to three years and nine months previously were revaccinated with New York City calf lymph virus and eighty-two of these, 25 per cent, responded with immune reactions, while 249, or 75 per cent, showed accelerated takes. Analysis of the data revealed that the proportion of immune individuals was fairly constant and bore no relation to the interval which had elapsed between the primary vaccination with cultured virus and revaccination with calf lymph. The percentage of accelerated reactions was slightly higher in the children revaccinated after one year and the reactions were more severe in this group, but little indication is had that susceptibility to calf lymph virus increased with the lapse of time within the limits of the observations. The differences in age at which the primary vaccinations were performed had no influence on the proportion of children who retained complete immunity during the period of observation. Seventy-eight of the 331 children who were revaccinated with New York City calf lymph received at the same time an inoculation with commercial calf lymph virus (A) and another group of eighty-two children received in addition to New York City virus an inoculation of commercial calf lymph virus (B). Of the seventy-eight children seventeen responded with immune reactions to New York City virus, while fifty-six responded with immune reactions to virus A; of the eighty-two children twenty-nine were immune to New York City virus, while forty-five

responded in that manner to calf lymph B. Sixty-six children whose records showed that they had had two successful simultaneous primary vaccinations were revaccinated dermally with New York City calf lymph from two to six months later. Eighteen responded with immune reactions, while forty-eight showed accelerated takes. Comparison of these figures with those obtained in the 331 children who received only a single injection of cultured virus for primary vaccination shows that the introduction of a double amount of this virus and the proportion of two primary lesions instead of one did not alter the percentage of children who retained for six months complete immunity to the New York City calf lymph. The authors suggest that primary vaccinations be made dermally with their cultured virus and that revaccinations will not become sick six months to a year later by means of a potent calf lymph virus. In this way vaccinated individuals will obtain a solid and lasting immunity to smallpox. Fifty-four children were inoculated intradermally with the cultured virus and from two to six months later they were reinoculated dermally with the New York City calf lymph virus. Twenty-one of these responded with accelerated takes, while thirty-three showed immune reactions. The accelerated takes were mild and healed quickly leaving only small superficial scars.

Epilepsy and Hypertensive States.—Having observed that headaches of migraine-like severity often accompany grand mal attacks or are found in the family of the epileptic patient, Pittam is of the opinion that spasm of cerebral vessels is probably the factor responsible. This does not explain the discharge of energy but, because in certain cases he has been able to control spasm in vessels of the extremities by the interruption of reflex pathways within the wall of the vessel itself, he felt that if he could do the same in the intricate plexuses of the carotid arteries it would be possible to affect the visible or objective

features of so-called epilepsy. Seven cases of epilepsy with good results in five, following carotid denervation, are reported. In three cases of hypertension with different symptoms the results of carotid denervation were also good.

Testosterone Propionate for Vascular Disease.—Edwards and his associates make a preliminary report on the effect of crystalline testosterone propionate in the treatment of seven male patients suffering from organic vascular disease. Three of the men presented typical signs of thrombo-angiitis obliterans and the other four were arteriosclerotic. In all seven patients the involvement was major, with loss of the popliteal, femoral and, in one case, the iliac pulsations. The signs and symptoms were marked, including small ulcerations in two of the patients with thrombo-angiitis obliterans. The testosterone propionate, dissolved in peanut oil, was given intramuscularly two or three times a week. Adjunctive treatment consisted only of general hygiene, except in the ulcer-free patient with thrombo-angiitis obliterans, who received eight hours of suction-pressure treatment. None of the patients have been followed for more than several months, as treatment of the first patient was started on July 23, 1938. Each of the patients showed a lack of skin arterialization by spectrophotometry which involved not only the diseased limbs but also the entire body. The administration of testosterone propionate showed an early and decided arterialization of the cutaneous blood. Moreover, the after-treatment curves likewise showed an inconstant diminution in the volume of blood in the more venous areas of the body. Other objective evidence of favorable change was an increase in the systolic pressure of from 6 to 26 mm. of mercury in the hypotensive members of this group and a lowering of hypertension in two cases. The ulceration in one patient with thrombo-angiitis obliterans has healed; the second has greatly improved. There was marked improvement in the walking ability of all the patients, with delay or abolition of intermittent claudication. Two patients were no longer subject to night pain, which had troubled them previously. Subjectively, the patients reported an increased activity and a feeling of optimism, results similar to those reported previously with this treatment.

Dermatitis and Fungous Infections Among Plate Printers.—Neal and Emmons studied the cutaneous lesions that occurred in a large printing establishment. There were 1,091 employees in the establishment. Of these, 378 had a severe exposure to inks and cleaning materials. The majority of the diseases occurred among these 378 men. In cleaning the hands, all printers from a given section washed in a common sink containing light mineral oil. Soap, stiff brushes, potassium carbonate, sand and paper towels were other cleaning agents used, and each man used one or more of these materials. Of the 365 men examined, sixteen had lesions which were classified as being of a chronic, eczematous, vesicular type; two had lesions of a chronic dry eczematous type; eight had, or showed evidence of having had, a folliculitis; three had lesions of a chronic, eczematous, fissure type, and three had evidence of dermatophytids. The duration of the dermatitis varied from one to thirty years. In most cases the lesions cleared when the patient avoided exposure to inks and cleaning materials and reappeared when he returned to work. Thirty-seven men whose hands were free from dermatitis at the time of examination had a past history of dermatitis of the hands. It was estimated that the total loss of working time because of dermatitis of the hands was thirteen years for one man during the period from 1910 to 1936. No dermatophytes were found by direct examination or by culture on the hands of any of the men with dermatitis, but they were found in cultures made from scrapings from the feet. There was no significant difference in the incidence of dermatophytosis of the feet in men with present evidence or past history of dermatitis of the hands and in those men not exposed to inks or without dermatitis. Men (121) exposed to inks (with or without dermatitis) and twenty-four controls were patch tested to inks and their component parts. Thirteen of the men exposed to inks gave positive reactions. No positive tests were obtained

among seventy patch-test controls. Of the plate printers tested who had dermatitis at the time of examination 50 per cent gave positive reactions. Of the plate printers with a past history of dermatitis of the hands 12.1 per cent gave positive reactions. Results of the patch tests with component parts of inks were variable. Recommendations for the control of the dermatitis include preemployment examinations and the exclusion from certain occupations of persons with a history of allergic disorders, constitutional conditions predisposing to cutaneous diseases and seborrheic disorders of the skin; periodic medical examinations to determine the incidence and cause of cases of dermatitis appearing in the plant; protective measures, proper materials and methods for cleansing the hands and full cooperation of the employees, and the provision of appropriate sanitary measures.

Hypothyroidism in Menstrual Disorders and Sterility.

—Mason asserts that a normal female sex cycle is dependent on the normal functioning of all the endocrine glands. This delicate hormone balance may be upset by an abnormal function of any one gland which is part of the chain. He particularly discusses the thyroid and says that hypothyroid states of far less degree than those of the typical textbook picture may be the cause of profound alterations in the female sex cycle, in which only one or two, or perhaps not any, of the textbook signs are present. In such cases the basal metabolism may be significantly low or it may be well within normal limits, and the diagnosis of hypothyroidism substantiated by the benefit to the patient of thyroid therapy. Rather than infrequent and scanty menstruation, combined with varying periods of amenorrhea, it has been the author's experience and that of others to find this relatively infrequently compared to the other extreme; viz., shortened menstrual intervals and menorrhagia. Frequently the bleeding is continuous, all rhythm being lost. Especially is this seen in the adolescent girl. By keeping the probability of hypothyroidism in mind as the etiologic factor in menstrual abnormalities, when gross pelvic pathologic conditions are absent, one can in most instances elicit other points which further direct attention to the thyroid. The one most commonly found is easy fatigability. Often a patient who has suffered from menorrhagia for months or years attributed her chronic exhaustion to the long continued excessive loss of blood. Unfortunately the doctor frequently does also and thereby misses the cue in diagnosis and treatment. Hypothyroidism is more frequent than is generally supposed. A thorough interest in the thyroid should be part of the study of every case of sterility, menstrual difficulty or recurrent abortions. Many cases of relative infertility and spontaneous abortions can often be explained on the basis of hypothyroidism, and this need not be of severe grade, that is an underlying endocrine imbalance. The administration of thyroid may safely be tried in all cases of menstrual disturbances when local pelvic causes cannot be found, when the basal metabolism rate is not significantly high, or in the absence of obvious signs or symptoms of hyperthyroidism. The chief guide to such treatment is the patient's response.

Chronic Constrictive Pericarditis.—Heuer and Stewart discuss nine cases of chronic constrictive pericarditis. Seven of the nine patients were subjected to operation. It was found that the arteriovenous oxygen difference was increased, the venous pressure was elevated and the circulation time was prolonged, while the cardiac output per minute, the stroke volume and the cardiac index were diminished. These values tended to, or actually did, return to normal. The clinical manifestations of this syndrome have been well described by White. The diagnosis of chronic constrictive pericarditis should be considered in the presence of signs of congestive heart failure not associated with the common etiologic causes. Patients with pericardial effusion in the absence of rheumatic heart disease should be kept under observation in order to detect the development of constrictive pericarditis. Tuberculosis as a cause of the disease was proved in only one of the seven cases in which operation was performed. While the results of surgical treatment undoubtedly are striking, a study of the surgical cases as reported in the literature shows that the primary mortality following decortication of the heart is still high (33 per cent). Of the 143 cases collected from the literature by the authors (exclusive of their own), death occurred in nineteen on the operating table and in twenty-eight during the immediate postoperative period. All seven patients with chronic constrictive pericarditis subjected to pericardiectomy have recovered. Three patients are cured in the sense that their symptoms and signs have disappeared and they are able to lead normal active lives, three patients are markedly improved and one patient is improved although sufficient time has not elapsed to make an accurate evaluation of the results of operation.

Knee Joint Tuberculosis.—Toumey states that from September 1915 to December 1936 knee fusion was performed in 222 cases of tuberculosis of the knee joint at the New York Orthopedic Dispensary and Hospital. Of these cases 199 have been followed from one to seventeen years after operation with an average follow-up period of five and one-half years. Fusion occurred in 196 of these cases. Fusion took place and the plaster cast was dispensed with at an average period of eight months after operation. The disease subsided in all but seven, in which sinuses persisted. Tuberculosis did not recur in any of the knee joints in which fusion took place. Fifty-nine patients were 10 years of age or less at the time of operation and fourteen were 5 years old or less. On the basis of his experience with operative arthrodesis of the knee joint for tuberculosis the author recommends this procedure for both children and adults. In no other joint in the body has such a high percentage of successful fusions been obtained.

Management of a Hay Fever Ionization Clinic: Comparative Statistical Survey of Results in 1937 and 1938. P. Franklin.—p. 871.

Asthma as Sequela of Nasal Injury.—Bourne asserts that nasal injury resulting in deformity was the precipitating factor in the development of asthma in two patients who had never previously shown any asthmatic tendency and have shown none in the considerable time that has elapsed since full recovery from operative repair. On the other hand, the great majority of cases of nasal injury have no sequela of this kind. A number of reasons may be suggested for the appearance of asthma in these two individuals. Doubtless unknown predisposing factors were present. In addition, the accidents produced severe trauma. The violence with which the girl struck the ground and the man the windshield was probably more than is involved in most nasal accidents. There was also an element of psychic trauma. Shock at the time, the possibility of police intervention, litigation in the civil courts and anxiety regarding means of livelihood were added. Further, and it is suggested that this is most important, other and more urgent injuries than those of the nose were present and owing to the immediate necessity of treating these injuries the condition of the nose and the nasal passages could not be determined in the early stages and was not investigated before discharge from the hospital. For these reasons deflection of the septum and scarring of the wound in the mucosa probably combined to produce a trigger area which, in patients whose nervous balance was disturbed, resulted in the sudden onset of acute asthmatic attacks, which appeared at intervals of from six to eight weeks. The presence of asthma in the two patients was no contraindication to operative treatment. Rapid relief and disappearance of attacks followed surgical intervention. The operation was that of simple resection and the author does not suggest that nasal treatment for asthma of other origin should take this form.

*External Operations on Frontal and Ethmoidal Sinuses. N. Patterson.—p. 235.

Some New Data Concerning Pathology and Treatment of Ozena. G. Hálász.—p. 245.

Operations on the Sinuses.—So far as the ethmoidal cells are concerned, whether the pathologic change is one of suppuration or polypoid formation or a combination of the two, the common practice has been to attack the disease by the nasal route. However, Patterson asserts that operation on the ethmoidal labyrinth through an external incision is becoming a recognized procedure in cases in which the disease is extensive or when one or more operations by the nasal approach have proved unsuccessful. The two possible objections to the external operation are that it may be more dangerous and that

a scar is produced, but operation through an external incision when conditions warrant such a procedure is probably safer than an attempt, and it can only be an attempt, to perform a radical operation by the nasal route. The author states that by employing the method which he describes scarring is negligible. In these "fronto-ethmoidal" cases he relies almost entirely on one or the other of two incisions. The "frontal" incision passes along the supra-orbital ridge and corresponds to the center of the hairy eyebrow or lies just below it. The "ethmoid" incision begins about one-fourth inch below the level of the inner canthus at the upper end of a sulcus or natural fold which can generally be seen passing outward and downward into the cheek. The incision is about 1 inch long. The skin should be sliced—not cut vertically to its surface—by holding the blade of the knife parallel to the skin to be incised. In this way a shelving edge of skin is obtained and when the time comes to close the wound such good apposition is obtained that approximation is very accurate and the resulting scar is generally almost invisible. The author states that the results obtained by the external ethmoid operation are most gratifying. In patients requiring radical treatment an accurate dissection replaces haphazard removal of polyps and bone, which is all that can be accomplished by the nasal route. The patient can be promised a nose permanently free from polyps, and when chronic suppuration is present in the ethmoidal labyrinth excision of the affected area would appear to be the only certain means of eradicating the disease. The author concludes that none of his patients have developed any serious complications and that meningitis need not be feared provided the operation is carried out with care and precision.

*Retrobulbar Neuritis with Pellagra in Nigeria. D. F. Moore.—p. 109.

Retrobulbar Neuritis with Pellagra in Nigeria.—Moore discusses a syndrome that occurs extensively in Southern Nigeria. It consists of perleche, sore tongue and genitalia and retrobulbar neuritis associated with optic atrophy. The condition has responded dramatically to treatment with autoclaved yeast products and so is believed to be pellagrinous. It is believed that gari, a dried parched manioc food, plays an important part in its incidence. The facts in support of pellagra as the cause of the syndrome in Southern Nigeria are that (1) throughout the palm-oil belt there is an abundance of cheap edible oil, (2) no single case of xerophthalmia has been seen in Southern Nigeria, (3) there is a great relative shortage of animal and fish protein in Southern Nigeria (it is in these areas, or under conditions that permit this shortage, that this syndrome is found) and (4) where gari is eaten to excess in the absence of the protein protective foods it is shown to have an almost constant relationship to the incidence of this syndrome. Gari bears a strong suggestive comparison with "spoiled maize." A nutritional policy based on the recommendations of the League of Nations Health Committee (1937) is required for Nigeria to include particularly the development of local food sources and when possible to abolish by replacement both gari and stockfish as dietary essentials of the people.

*Primary Peritonitis in Scarlet Fever Treated with Sodium Salt of Sulfa-pyridine. H. S. Banks.—p. 983.

Specific Immunity in Osteomyelitis.—Valentine and Butler have tried to follow the development of specific antibodies in the serum in cases of acute staphylococcal osteomyelitis and to correlate the results with the clinical severity of

the infection, the persistence of bacteremia and the outcome of the disease. Since there is no reason to suppose that β -hemolysin is of importance in human infection, attention has been concentrated on the α -hemolysin, leukocidin and their antitoxins and on the agglutinin. The cases described include seven cases of acute osteomyelitis in which survival occurred, two of fatal pyemia associated with osseous infection and one of pyemia with no osseous involvement. The study shows that in response to deep-seated staphylococcal infection in man the spontaneous production of antileukocidin bears a close relation to the severity of the clinical condition. No evidence has come to light suggesting that antihemolysin (α) is likely to be of much value in treatment during the acute stage of the infection. There is some indication that the disappearance of staphylococci from the blood stream in acute osteomyelitis may often coincide with the appearance of agglutinins in the serum. In at least two cases, those in which there are pelvic lesions, there was evidence of continued spread of local infection after an apparently satisfactory level of general immunity was established. It is hoped that by improving the general condition of the patient in the first week by the use of antitoxin the resistance of the tissues at the site of infection may be increased. Pyemia is the result of septic venous thrombosis, which may occur either in association with the osseous lesion of osteomyelitis or with a superficial, apparently minor, focus. It is suggested that such a minor focus may in some cases be the main source of bacteremia and of any further lesions which may develop in the course of the illness.

Primary Peritonitis in Scarlet Fever.—Banks reports a case of hemolytic streptococcus septicemia and general peritonitis which occurred on the twenty-sixth day of scarlet fever and was associated with infra-orbital cellulitis, cervical adenitis and nephritis. The patient had not had the benefit of antitoxin treatment in the initial stage of the scarlet fever but had been treated with sulfanilamide, which was badly tolerated. For the peritonitis, since there was no evidence of an abdominal focus, operative treatment was not adopted. Treatment, at first with sulfapyridine by injection of the 20 per cent suspension of the drug, later by injection of the sodium salt and ultimately by oral administration, apparently brought about a rapid sterilization of the pus in the abdominal cavity. The subsequent accumulation of peritoneal fluid was removed by repeated aspirations. There was also an associated bilateral pleural effusion. The patient suffered in convalescence from a profound secondary anemia, which did not improve under iron and liver therapy but rapidly improved after two blood transfusions. He made a good recovery. The advantage of injections of the sodium salt of sulfapyridine in the early treatment of this type of case is emphasized.

Changes in Nails as Aid to Diagnosis.—Low maintains that few medical men, when examining a patient, make even a cursory inspection of the nails. Yet a good deal of information can sometimes be obtained from these structures. Their

normal growth depends on the general health and they are quick to show changes when that is interfered with. When all the nails of the hands and feet show the same alteration the presumption is that it is due either to a congenital anomaly or, in the absence of any adjacent skin inflammation, to some general condition affecting all the nails through the circulation. When only some of the nails are affected and others are quite normal, a local cause should be looked for such as a recent or remote injury, an infection of the nail itself (as in ringworm) or an inflammation or growth affecting the skin or deeper tissues round the nail. The fact that the nails are affected in any general condition indicates to some extent its severity and so may influence the prognosis. A change in the color of the nails may be diagnostic of leukonychia, trophic nerve disturbances, arsenical poisoning, Addison's disease, argyria, chronic mercurial poisoning and diabetic and other forms of gangrene. Apart from any alteration in color the nails may become altered in shape and size in various ways, as clubbing of the fingers and toes in chronic pulmonary and cardiac conditions. The opposite condition may also occur. The cause of spoon-nail is not known. It may occur in association with nutritional anemias. As most of the persons in whom it occurs are of the highly strung type, the nervous system may play some part in the etiology. Fragility and splitting of the nails are fairly common. Some persons are born with nails which are brittle and tend to split and break off at the free ends. A similar condition may also be acquired by prolonged or frequent contact with chemicals (as in manicuring), especially alkalis. There is also the condition known as egg-shell nail, in which the nail-plate is soft, is semitransparent, bends easily and splits at the end. This particular change has been reported in association with arthritis, peripheral neuritis, leprosy and hemiplegia. A somewhat similar condition also occurs occasionally in late syphilis, producing onychia syphilitica sicca. In this condition all the nails are affected. They are dry and atrophic and tend to split. It may be the only visible sign of syphilis, but the diagnosis can be confirmed by the Wassermann test. Longitudinal striation of the nails is a common condition in adults past middle life. In slight cases it is merely an exaggeration of the normal longitudinal ridges of the nail bed, but in well marked cases it is accompanied by splitting of the nails (onychorrhexis) at the free margins. It is common in persons who are absorbing from a focus of infection at the root of a tooth or in the bowel. In addition to cases due to focal infection, lining of the nails is seen in gout and nervous diseases such as neuritis and hemiplegia. It is also associated with the dry skin and scanty hair of myxedema. Dryness of the skin and lusterless nails showing longitudinal or transverse lining is also seen in cases of vitamin A, B and D deficiencies. Administration of the appropriate vitamins in these cases will restore the nails to normal. A single raised longitudinal ridge running down one nail is the result of a scar at the base of the nail from previous disease or injury. Transverse lines, usually known as Beau's lines, appear on the nails as a result of previous interference with the growth of the nail matrix. If these lines are due to a local inflammatory cause, usually the nails are not all affected. Shedding of the nails may occur in epidermolysis bullosa, after fevers and in extensive cutaneous diseases. Atrophy of the nails is often associated with ectodermic defects such as extreme thinness or absence of scalp hair. Although not necessarily associated with any mental condition, this change in the nails is fairly frequently seen in mentally defective children. It may also be an acquired condition and may follow injuries, scars from disease, frostbite, sclerodactylia, Raynaud's disease, radiodermatitis and syphilis. It also occurs in hyperthyroidism and exophthalmic goiter and has been reported after nerve injuries, in leprosy, tabes dorsalis and syringomyelia and in prolonged debilitating diseases such as cancer. Thickening and hypertrophy of the nails may occur in chronic eczema with hyperkeratosis of the palms and soles, chronic cutaneous disease, ringworm, paronychia, peripheral neuritis, leprosy, tabes and hemiplegia. Pituitary and thyroid dysfunctions may be responsible for a few cases, but in the majority of cases there is no evident cause except want of cleanliness and neglect.

*Dietetic Treatment of Diabetes by Diet Relatively Rich in Glucides. I. Teleman.—p. 387.

Glucides in Diabetes.—Teleman points out that, although insulin is of great significance in the treatment of diabetes, the diet remains nevertheless the most important factor of the therapy of this disease. The author shows that a diet which is relatively rich in glucides counteracts the subjective symptoms, averts the peril of coma and contributes to the improvement of the metabolism. He compared the results of this diet with other diets. He reports three cases in which different types of diets were used. A man aged 62 complained of severe headaches and other diabetic symptoms. He had received insulin and a diet in which the carbohydrate intake was restricted to from 80 to 100 Gm. but which had high fat and protein contents. The diet suggested by Porges and Adlersberg provides 300 Gm. of carbohydrates and small amounts of fats and proteins (60 Gm. of each). The patient followed this regimen for three weeks and under its influence the subjective symptoms disappeared, his general condition was much improved and the glycemia and the urea content were less than with the other diet. After the patient had returned for a month to the old diet with restriction of the carbohydrates, tests revealed a renewed increase in glycemia and in the urea content and the general condition was greatly impaired. Convinced of the superiority of the diet with the high carbohydrate content, the patient thereafter voluntarily resumed it. After reporting two similar cases, the author discusses the theoretical foundations of this diet with the high carbohydrate content. He stresses that sugar is an indispensable food for which the diabetic patient has the same need as has the normal person and that care must be taken that the intake and utilization of carbohydrates is sufficient and compatible with the nutritive equilibrium. The essential characteristic of diabetes is a blockage of the utilization of the glucides because of a lack of insulin, which produces cellular hunger by exhaustion of the glycogen in the tissues. The augmented glycemia and the glycosuria must be regarded as compensatory phenomena; they reflect the gravity of the disease but are only secondary symptoms. The treatment of diabetes mellitus must have as its principal aim the enrichment of the organism in utilizable glycogen with the aid of carbohydrate foods. The quantity of calories administered to a diabetic patient should be reduced to a minimum compatible with the nutritive equilibrium and the conservation of a normal weight. The different types of nutrient substances must be apportioned in accordance with the severity of the disorder and the weight of the patient. In the mild forms of diabetes mellitus which do not require insulin therapy, the glucides and proteins should amount to 40 per cent each and the fats to 20 per cent; in the grave forms in which insulin must be given, the glucides should represent 50 per cent, the proteins from 20 to 30 per cent and the fats 20 per cent.

Symptomatology of Chronic Tophaceous Gout. F. Francon.—p. 840.

*Present Status of Prophylaxis of Sudden Death by Pulmonary Embolism. J. Rouffart-Marin.—p. 845.

Pulmonary Embolism.—Rouffart-Marin shows that a knowledge of the mechanism of the sudden death by embolism will permit a more effective treatment and will aid in the prevention of this grave postoperative complication. Citing the various anatomic lesions of pulmonary embolism that are detected on necropsy, the author directs attention to the disproportion which often exists between the anatomic lesion and the serious disorder which they provoke; that is to say, a small clot may cause sudden death. The diagnosis of postoperative embolism may prove simple and yet there are some authors who consider it difficult, and experienced surgeons have been

known to make erroneous diagnoses of postoperative embolism. Bardin introduced beads into the external jugular vein and found that beads of extremely small caliber which are incapable of impeding the circulation may cause sudden death and he was able to prove that it is the result of a nervous reflex elicited by the embolizing particles on the nervous terminations of the pulmonary arteries. Bardin's observations demonstrated the importance of the sympathetic nervous system in the pathogenesis of postoperative embolism and the prophylactic value of neurosympathetic medicaments. After mentioning other investigators who studied this problem, the author says that he observed thirteen cases of grave pulmonary embolism with ten deaths. After reviewing these cases, he discusses the treatment. He says that in one case he decided to try Trendelenburg's operation but the patient died before it could be carried out. About the medical treatment he says that in the cases which are referred to as grave pulmonary embolism, and which in reality are only pulmonary shock, the therapy must be based on the clinical symptomatology. For cases of embolism of the syncopal form he recommends artificial respiration, oxygen therapy, ephedrine and atropine; for the anginal form morphine, heroin, papaverine, atropine and stellate anesthesia; in the asphyxial form papaverine, sympathicomimetics, respiratory analeptics and oxygen; in collapse, sympathicomimetics, epinephrines, ouabain and respiratory analeptics; in infarct, heroin, papaverine and so on. The peripheral vascular analeptics must be given in large doses. Moreover, the action of these medicaments is favored by the intravenous injection of sodium bicarbonate. In the syncopal form with cardiac arrest, the author was able to save the life of several patients by the intracardiac injection of caffeine, a camphor preparation, epinephrine and atropine. The author further stresses the importance of certain prophylactic measures.

*Rapidly Fatal Encephalitides in Children. C. Gardère, M. Dauvergne and G. Bertrand.—p. 281.

Encephalic Metastases and Cerebral Tumors. J. Dechaume, P. Wertheimer and L. Mansuy.—p. 287.

Mematologic Memorandum for Diagnosis and Prognosis of Pulmonary Tuberculosis. Vincenti and Gausson.—p. 303.

Rapidly Fatal Encephalitides in Children.—Gardère and his associates point out that certain acute encephalitides in children are noteworthy for their particularly rapid development and their exceptional gravity. The encephalitides with rapid death are those in which the evolution does not go beyond the third day. This form seems to appear especially in nurslings. Of forty-three cases, seventeen concerned infants of the first year, nine of the second year and the other seventeen concerned children between the ages of 2 and 12 years. This encephalitis with rapid death is most frequently of the para-infectious type (thirty-four of forty-three cases). Whooping cough seems to be the most frequent causal infection during the first two years of life, and measles during the later years. Varicella and vaccinia are less often the cause. Some cases seem to be primary and their cause is still obscure, but at times they may be of influenzal origin and in other cases a connection with lethargic encephalitis may be considered. The symptomatology is characterized chiefly by convulsions, somnolence and coma. But what is especially characteristic for these forms is the almost immediate appearance of symptoms indicating bulbar involvement: irregularity of the respiratory rhythm and tachycardia. Lumbar puncture usually yields a normal cerebrospinal fluid or one with slight lymphocytic reaction. After reporting six cases the authors discuss the pathologic anatomy. The anatomopathologic studies are as yet few in number but they reveal the usual diffuse lesions of encephalitis with involvement of the bulbar centers, where cytologic lesions are found in spite of the rapidity of evolution. The diagnosis is especially difficult in the primary forms. In nurslings the possible existence of a suppurating otitis or of a mastoiditis must be considered, for these may produce a similar symptomatology. The outcome of the peracute forms of encephalitis is usually rapidly fatal, although occasionally the bulbar symptoms subside and the child recovers.

Protamine Zinc Insulin in Treatment of Diabetes Mellitus. G. Camerini.—p. 671.

*Bronchography in Diagnosis of Primary Cancer of Lung. C. Scarinci and F. Vitagliano.—p. 680.

Bronchography in Diagnosis of Pulmonary Cancer.—Scarinci and Vitagliano call attention to the importance of the roentgenologic examination of the lung and bronchi for an early diagnosis of primary cancer of the lung. The examination includes (1) radioscopia, (2) roentgen examination of the lung and (3) bronchography under radioscopic control. The latter is the most important phase of the roentgenologic examination of the structures. It is done with the purpose of ascertaining the presence of bronchial stenosis, which is constant in all cases of cancer of the lung, early in the development of the disease. In making radioscopic bronchography the following technic refinements are of importance: (1) inducing a perfect anesthesia to prevent coughing, (2) introducing the iodized oil through an intratracheal sound as far as possible into the bronchi and (3) injecting the oil slowly and under radioscopic control. The posture of the patient during the examination varies with the location of bronchial stenosis (as suspected from the results of the examination of the thorax and by previous radioscopia and the roentgen examination of the lung). According to the authors, radioscopic bronchography is of more diagnostic value than bronchoscopy in cancer of the lung. The value of bronchoscopy is limited to the diagnosis of cancer when it is located in lobes of the lung which correspond to bronchi which are accessible to bronchoscopic examination and not otherwise. A diagnosis of cancer in the upper lobe cannot be made by bronchoscopy. The entire bronchial tree and the points at which the opaque substance stops from stenosis can be seen during radioscopic bronchography. Moreover, an early diagnosis of cancer of any lobe at any distance from the hilus, and either in the lung, the bronchi or the bronchiole, can be done by radioscopic bronchography. Bronchial stenosis shows diminution (or complete closure) of the lumen of a given bronchus by either intrabronchial cancer or by external tumoral compression. When it is present in association with some other clinical symptoms of cancer of the lung, it is a diagnostic sign of almost absolute value. The authors emphasize the diagnostic significance of bronchography, especially because of the fact that cancer of the lung can be controlled (according to the literature) without any recurrences by early surgical operation (exeresis of the involved lung or pneumonectomy). They report two cases of cancer of the upper and lower lobes, respectively, in which the diagnosis was made by radioscopic bronchography.

Malignant Exacerbation of Multiple Sclerosis.—Juba thinks that for the clarification of the relations between multiple sclerosis and encephalomyelitis disseminata, as far as this is morphologically possible, those cases of multiple sclerosis are especially suited in which death resulted from a peracute exacerbation. He describes three microscopically verified cases of multiple sclerosis in which, after a chronic or intermittent course, a peracute exacerbation set in. Death followed in the first case after thirteen days, in the second after seventeen days and in the third after five days. In the first case, of hemiplegia, the anatomic examination disclosed in the medullary substance of the hemispheres many perivascular, encephalomyelitic foci with indefinite outlines. Formation of glia could be observed in a young focus of the wall of the lateral ventricle.

In the second case, of tetraplegia with spastic and bulbar symptoms, a sharply defined, new destruction of the medullary substance was demonstrable in the upper cervical section and in the closed oblongata. In the third case the spastic paraparesis was suddenly transformed into a flaccid paralysis; in the anterior horns of the spinal cord, sharply defined, symmetrical foci were found, the central portion of which had broken down. As common characteristics of the acute process the author detected the formation of glial foci around the vessels and around the fluid space with special affinity for the white substance; at any rate, the ganglion cells remained relatively free. As far as the morphologic aspects are concerned, there are doubtless close relations to encephalomyelitis disseminata. Especially characteristic is the rapid growth of the foci, so that the process is not restricted to the juxtavascular region but penetrates deep into the parenchyma; then there is the sharp demarcation and the severe inflammation, which together give a characteristic aspect to the acute phase of multiple sclerosis. If these characteristics are accepted as criteria of the acute phase of multiple sclerosis, and if the morphologic aspects of the cases of encephalomyelitis disseminata are considered, it seems probable that there is a form which belongs to the group of multiple sclerosis and is an especially malignant type of multiple sclerosis. On the other hand, there are cases which have no connection with multiple sclerosis and which, as regards their structure, closely resemble the para-infectious encephalomyelitides. About the pathogenesis the author says that he adheres to the inflammatory character of multiple sclerosis. He admits that the foci usually form around the vessels but says that they also form around the fluid spaces. He does not share Putman's theory of the causal significance of circulatory disturbances and especially of the formation of thrombin in the small vessels; Juba neither detected thrombi nor observed that the process was restricted to the perivascular region.

Cataract of Diabetes Mellitus.—Bücklers describes his observations in a case in which changes in the lenticular turbidity were recorded continuously and metabolic tests were made simultaneously. A tabular report indicates the gradual retrogression of the cataract, the sugar content of the urine and blood, the specific gravity of the urine, the water balance and the dose of insulin that was administered. The retrogression of the turbidity of the lens began in the axis and advanced in an irregular manner toward the periphery, but it seemed to be more rapid on the temporal side. The table discloses that the subsidence of the turbidity was already noticeable at a time at which there still existed a considerable metabolic disturbance. One increase in the blood sugar was accompanied by a slight increase in the turbidity of the lens, but a second increase in the sugar content caused no lenticular changes. It cannot be decided whether the decrease in the visual acuity was caused by a lenticular turbidity or by a change in the refractive power during the temporary hyperopia. The author believes that the two processes developed simultaneously. In trying to find an explanation for these two disorders, the author cites the theory advanced by Granström for the development of the diabetic impairment in the refraction and the one advanced by Braun for the pathogenesis of the lenticular turbidities. Both of these authors ascribe great importance to the disturbance in the mineral and water exchanges. The turbidity in the lens as well as the transitory hyperopia are apparently due to a temporary increase in the water content of the lens.

Hormone of Ovum.—Klar says that it is generally assumed that the cyclic changes of the uterine mucosa take place under the influence of estrogen and progesterone and that menstruation sets in as the result of a sudden decrease in progesterone, which in turn is caused by the death of the corpus luteum. This sudden death of the corpus luteum as yet has found no satisfactory explanation. The fact that the corpus luteum is destroyed only when the ovum is not fertilized suggests that the ovum plays an active part in the onset of menstruation. It seems likely that the resorption of the dead ovum liberates hormonal substances, which cause the death of the corpus luteum and thus the onset of menstruation. Whether the dead or dying ovum influences the female sexual cycle has been answered neither positively nor negatively. To determine the endocrine action of the dying ovum, the author made experiments with an extract of fish roe and with extracts of the urine of menstruating women (collected urine of the first day of the menstrual flow). Assuming that the production of abortion in pregnant mice would be a simple test method, the author made experiments on pregnant mice. These revealed the presence of a substance which elicits abortion, apparently as the result of premature detachment of the placenta, during all stages of gestation. The length of time that is required for the elicitation of the abortion is dependent on the dose. This time factor makes possible the quantitative determination of the required dosage; the quantity that elicits abortion in the pregnant mouse within ten hours after the administration is designated as one mouse unit. The substance was tested also on rabbits and it was found that abortion is caused by approximately 200 mouse units. The author cites factors which indicate that the abortifacient effect of the substance extracted from fish roe is not due to one of the fish toxins. In the summary he stresses the following points: 1. A substance can be extracted from ova which regularly elicits premature birth in mice and rabbits. 2. A substance with the same action can be obtained in many but not in all cases from the urine of menstruating women. 3. On the basis of the chemical behavior it is suggested that the substance in question, which as yet has not been isolated, represents a protein body of a low order. 4. These results make an endocrine action of the dead ovum highly probable.

Perforated Gastric and Duodenal Ulcer.—Geisthövel discusses the diagnosis and treatment of gastric and duodenal ulcers. He bases his discussion on observations he made in 100 cases. He thinks that the general practitioner can readily recognize a perforated ulcer on the basis of the anamnesis and the clinical aspects, provided, of course, he sees the patient early enough. If a physician is called only after peritoneal symptoms have already developed, it may be difficult to determine the cause. The question whether the first operation should be conservative or radical has not been definitely decided as yet. The author is of the opinion that, on the whole, it is

advisable to try to effect cure in a single operation. In his material the primary resection was performed in twenty-six cases. Most of these patients were comparatively young (average age 34 years) and the operation was nearly always performed in the course of the first six hours after the perforation. In none of the cases in which extensive resection was decided on had more than twelve hours elapsed since the operation. He points out that the mortality increases with the length of the time interval. To be sure, other factors, particularly the patient's general condition and the local aspects, that are detected when the abdomen is opened, are important factors in deciding the type of surgical intervention. Following the evaluation of the palliative resection (resection for exclusion according to Finsterer), the author says that in twenty-four of his patients resection according to the second method of Billroth was done. Billroth's first method was performed in only two of the cases, for this method involves considerable dangers. The author stresses as an advantage of the primary resection that it removes simultaneously the ulcer as well as its cause, the "acid producer," and thus prevents relapsing ulcers and other sequels. If the first operation is a conservative procedure in the form of simple suturing, the secondary resection should be made soon after, because simple suturing is often followed by a new perforation, by stenosis or by cancer. In secondary resections the duration of the operation is usually prolonged as the result of adhesions. The author regards the prophylactic operation of the ulcer as the best treatment. It has been proved by statistics that the duodenal ulcers of the anterior wall perforate most frequently and the prepyloric ulcers have the greatest tendency to malignant degeneration and to penetration into the pancreas. He thinks that these types should be subjected to surgical treatment if, after two or three internal treatments, they have not subsided.

Juxtacardiac Gastric Ulcer.—Finsterer maintains that the juxtacardiac ulcers hold a special position not only because of their relative rarity but also because their diagnosis and treatment are rather difficult. In a critical analysis of the results which he obtained in the surgical treatment of juxtacardiac ulcers he finds that the mortality rate was comparatively high in his material because, in some difficult cases in which the resection of the ulcer was forced, Madlener's operation should have been made. To reduce the acidity in juxtacardiac ulcers, Madlener removes the distal half of the stomach together with the pylorus but leaves the ulcer untouched and makes the anastomosis with the duodenum according to the first method of Billroth. Finsterer says that in the future he intends to resect the ulcer only if by gastrotomy and by intragastric palpation it has been determined that the ulcer is far enough removed from the esophagus that a secure closure of the gastric stump can be obtained. For all other cases he recommends Madlener's operation, which permits a reduction in the surgical mortality and also insures better permanent results than does simple gastro-enterostomy. The latter method should be employed only in exceptional emergencies. The author thinks that in the interest of the patients it is better to perform Madlener's resection too often than not often enough in cases of juxtacardiac gastric ulcer.

Late Results After Cholecystectomy.—A follow-up study of 400 patients operated on at the Medical Institute of Odessa, according to Sosnovskiy, revealed a complete clinical recovery in 82.5 per cent, improvement in 12 per cent and failure in 10

improve in 5.5 per cent. Recurrent manifestations were present in 4.2 per cent after operations for uncomplicated cholecystitis, in 18 per cent after operations for cholecystitis with complications of medium severity and in 34 per cent after operations for cholecystitis associated with severe complications. Recurrence of pain was present in 25.5 per cent of all cases. In 8 per cent there was pain which lasted for from one and one half to five months and was followed by a complete clinical recovery; in 12 per cent the pain recurred for a period of from one half to three years and was followed by considerable improvement, while in 5.5 per cent pain was present for from three to eleven years and there was no improvement in the clinical condition of the patient. The author concludes that an early and timely operation when the inflammatory process is localized in the gallbladder and does not involve the adjacent viscera is essential to the obtaining of satisfactory late results. Cholecystectomy is the operation of choice in cholecystitis. It results in a small mortality rate and is rarely followed by a recurrence. Cholelithotomy with drainage of the hepatic or the common bile duct is indicated in obstruction of the bile passages complicated by cholangitis, hepatitis or pancreatitis. Drainage of the duct may be omitted on the removal of the obstruction, in the absence of complications and with a patent papilla of Vater. Cholangitis, hepatitis and pancreatitis were the more frequent causes of recurrence. In the majority of the cases these causes were associated with one another. Among the less frequent conditions the author lists stones overlooked at the time of operation, strictures and obliteration of the deep biliary ducts, dyskinetic disturbances and adhesions. Operation undertaken for stasis gallbladder is seldom followed by relief in view of the fact that stasis of bile is brought about by dyskinetic disturbance, the treatment of which is essentially conservative. Because of multiplicity of factors the exact cause of a recurrence cannot be easily ascertained in most cases. Aspiration of duodenal contents, mineral waters, physical therapy, mud baths, a dietetic regimen, nupercaine hydrochloride blockade after Speranskiy, infiltration of Head's zones, and psychotherapy are the therapeutic measures first to be tried in the treatment of recurring manifestations. A secondary operation is indicated when conservative measures fail and when indications of a stone in the choledochus, of a stricture of a duct or of adhesions in the vicinity of the gastric antrum or the duodenum are present. The author concludes that the problem of prevention of recurrences after cholecystectomy depends on unanimity between surgeons and internists as to operative indications. Only an early and timely operation is capable of further reducing the mortality rate and the incidence of failures.

Quick's Test of Hepatic Function.—Lindeboom directs attention to a test of the hepatic function which was first suggested by Quick and was described in the *American Journal of the Medical Sciences* 185:630 (May) 1933 (abstracted in *THE JOURNAL* Sept. 2, 1933, page 101). The test is based on the secretion of hippuric acid following the administration of sodium benzoate. The author found that the test reveals disturbances not only in renal diseases with nitrogen retention but also in many hepatic disorders such as obstructive jaundice, cardiac engorgement of the liver, hepatitis and cirrhosis. He thinks that as yet the test cannot be recommended for routine use in the clinic. Nevertheless it is of theoretical interest that the synthesis of hippuric acid may be employed as an indicator

of an impairment of the hepatic parenchyma. Moreover, the test can be used to obtain information about the course of a hepatic disorder. It is also of interest that the test reveals abnormal values in many cases of catatonia.

Diagnosis of Gout.—Brøchner-Mortensen says that it is well known that during the first twenty-five years of this century the incidence of gout diminished considerably but that during the last few years it has increased again. Even though this change of incidence is unquestionable, the fluctuations are strongly accentuated by simultaneous variations in the nosographic delimitation of the morbid picture. In his paper the author reviews the different diagnostic criteria of gout on the basis of the literature and of his own studies on thirty patients with typical gout. He shows that the anamnesis and the observation of the acute attack are most reliable diagnostic aids. Subcutaneous uratic topi (verified by the murexide test) are pathognomonic for gout, but they are an inconstant and, in the majority of cases, tardy symptom. Roentgenologically detectable defects resembling topi in the bones occur earlier and more frequently, but they are not pathognomonic for gout. Hyperuricemia is found in 75 per cent of the cases, being an almost constant symptom when the disease has existed for some years, but it may be conjoined with other disorders. The endogenous excretion of uric acid is normal in cases of gout. The renal function measured with the creatinine and urea clearance is normal in the majority of the cases. There is no relative reduction of the uric acid clearance as compared to the creatinine and urea clearance. After intravenous or oral administration of purine an increase of the uric acid clearance amounting to at least 50 per cent, and often more, is found in normal persons. In patients with gout, a less marked increase of the uric acid clearance is generally found, but in some cases the reaction after administration of purine is found to be normal. Attempts at provoking acute attacks by administration of a diet rich in purine or of a ketogenic diet for a prolonged period as a rule gave negative results. After a ketogenic diet the uric acid excretion is found to be reduced but the renal function on the whole is not changed. Mostly, though not always, the sedimentation rate of the red blood corpuscles increases during an acute attack of gout. Examination of the blood picture revealed polycythemia in three patients. Fourteen of the thirty patients with gout were found to have a slight impairment of the hepatic function or lesions of the hepatic parenchyma. The author examined cases in which the diagnosis of atypical gout had been considered. However, none of these cases afforded a clue which would justify this diagnosis. Anamnesis and articular symptoms were not typical. Hyperuricemia and true topi were absent. Exogenous administration of uric acid gave normal reactions. On the other hand, defects resembling topi in the bones were found in several cases. Nevertheless the author is of the opinion that, theoretically, the occurrence of atypical cases cannot be excluded.

Lymphocytopenia and Fever.—During the treatment of rheumatoid arthritis with gold salts, Sundelin observed transient lymphocytopenia. This lymphocytopenia, which in the majority of cases was severe, made its appearance some few hours after the injection and was accompanied by a feeling of malaise, poor general condition, high fever and a number of other symptoms. After some hours, at most after twenty-four hours, the acute

symptoms disappeared and the blood picture regained its normal appearance. The question arose whether the gold salts caused the lymphocytopenia or whether it was simply a symptom accompanying the fever. To throw light on this problem the author made experiments with artificially induced fever. In thirty-five persons fever was produced with injections of various types of vaccine, in two with protein injections, in four with injections of sulfur and in seven with hot baths and packs. Studies were made also on two patients with sepsis and on two patients undergoing malaria therapy. In the summary the author says that his material is too small to permit generalizing conclusions, but he thinks that it is sufficiently large to establish that the transitory extreme lymphocytopenia which appears first after unspecific fever therapy and secondly in other fever conditions is a biologic reaction which, on the whole, runs inversely congruent to the fever. Theoretically the observation gives rise to questions about the origin of the lymphocytes, their task and fate, and, last but not least, the central nervous regulating mechanism by which both the morphologic and the chemical constituents of the blood appear to be controlled.

Fate of Transfused Erythrocytes.—Dekkers shows that there is no general agreement about the length of time for which the transfused erythrocytes remain in the circulation of the recipient. The survival time given in the various reports varies between eight hours and 100 or more days. This divergence in opinion is chiefly due to the fact that the transfused erythrocytes could not be detected directly in a specimen of blood, withdrawn after transfusion, and studies had to be made mostly with indirect methods. By means of the "hetero-agglutination factors" M and N described by Landsteiner and Levine, the direct detection of the transfused red blood corpuscles became possible. Using this improvement the author followed the fate of the transfused erythrocytes in thirty-two patients. In all, thirty-five transfusions were given to these thirty-two patients. The method used by the author makes it possible to detect the erythrocytes of the donor by means of "direct differential agglutination tests" which use M and N test fluids. The cases were selected in such a way that the erythrocytes of the donor contained a factor (M or N) which the erythrocytes of the recipient did not possess, donor and recipient belonging to the same iso-agglutination group. On the basis of his studies the author arrives at the following conclusions: 1. The described method is suitable for the determination of the length of survival of transfused erythrocytes. 2. The transfused cells could be observed for a considerable time. They disappeared gradually from the circulation of the recipient. 3. In cases in which 500 cc. of blood was transfused and an unfavorably acting factor from the side of the recipient could be excluded, the average time during which the erythrocytes of the donor were detectable was from fifty-four and one half to seventy-five and one half days. 4. The following factors appeared to influence this time: (a) the normal time of existence of human erythrocytes, (b) the quantity of transfused blood and (c) the condition of the recipient. An unfavorable influence was seen in a patient suffering from hemolytic jaundice. 5. No sensitization occurred in the first four or five transfusions with blood containing a hetero-agglutination factor. 6. In the treatment of serious acute and chronic anemias, transfusion of blood is by far superior to infusion of other fluids. 7. Although the time of survival of human erythrocytes could not be determined exactly with this method, the results of these investigations give evidence that it is much longer than is generally assumed; it may be three months and more.

2: 1147-1226 (April 22) 1939

*Extrapleural Pneumothorax, With Special Reference to Cases of Pulmonary Tuberculosis Regarded as Not Able to Bear Thoracoplasty. J. Holst and E. Refsum.—p. 1147.

Extrapleural Pneumothorax.—Holst and Refsum performed extrapleural oleothorax or pneumothorax on thirty-eight patients too weak to allow other treatment. One patient died three weeks later, perhaps as an indirect result of the operation. One died thirty-two days after the operation from mixed infec-

tion and progression of the tuberculous process. Of the twenty-two patients treated for from two to ten months, thirteen are for the time being abacillary, with obliteration of the cavity. The authors find the results encouraging but do not at present consider extension of the indications justified, as the material is too small and the time of observation not long enough for evaluation of the uncertain factors, chief of which is the danger of infection.

Hospitalstidende

*Subacute and Chronic Myocardial Lesions Due to Blunt Traumas. E. Warburg.—p. 1157.

Myocardial Lesions Due to Trauma.—Warburg says that there is no form of myocardial insufficiency or of symptoms from the heart musculature on the whole which cannot be caused by nonpenetrating trauma. Arteriosclerosis and hypertension were predisposing factors in at least eleven of the thirty-eight cases discussed. As a rule the trauma was localized to the thorax. A latent period of several days may elapse between the trauma and the appearance of grave symptoms from the heart. In one instance several months passed before more marked symptoms set in. A varying electrocardiogram is of great value in the diagnosis of traumatic disturbances of the heart musculature, and a persisting abnormality of the electrocardiogram is also of interest; almost every known electrocardiography anomaly, except some rare arrhythmias, occurs in the material. The electrocardiogram may be normal. In some cases recovery takes place after a few weeks; in numerous cases a chronic heart insufficiency develops which more or less rapidly leads to death. Of the thirty-eight patients nine died, seven of these from ten days to two years after the trauma. Patients with heart lesions due to blunt trauma, the author says, are treated in the same way as other patients with disorders of the heart musculature. The large number of traumatic coronary occlusions confirm his earlier view that these heart lesions should not be treated operatively.

*Angina Pectoris with Xanthomatosis: Hereditary Disease. C. Müller.—p. 1183.

Weil's Disease Due to Rat Bite. C. H. Bie.—p. 1191.

Angina Pectoris with Xanthomatosis.—Müller says that xanthomatous heart disease is frequent and reports seventeen families in which heart disease due to xanthomatosis was inherited as a dominant factor. In ten of the families there was angina pectoris and xanthoma tuberosum alone or in combination with xanthelasma, in six angina pectoris and xanthelasma, in three angina pectoris without xanthoma or xanthelasma but with other conditions pointing to xanthomatosis as an essential cause. Of the seventy-nine persons included, thirty-five were examined personally. Xanthomatosis causes a special form of arteriosclerosis distinguishable etiologically and clinically from the usual arteriosclerosis. While the xanthomatous deposits may cause valvular defects, they far more often lead to changes in the coronary arteries with angina pectoris. Cardiac disorder may appear in young persons but is more often seen in middle-aged and old persons. It may be chronic and long continued or may cause sudden death. Symptomatically this form of angina pectoris does not differ from the usual form. Heart infarct is common. Hypercholesterolemia, established in all of the cases examined, was highest in those in which xanthoma tuberosum existed. There was no regular relation between the changes in the skin and the degree of hypercholesterolemia. Hypertension was rare. Both xanthoma tuberosum and xanthelasma are sometimes so little prominent that they may easily be overlooked on clinical examination. Confusion with other diseases of the skin may also occur. In hereditary heart disease in which rheumatic fever, syphilis and hypertension are excluded, xanthomatosis should be borne in mind as the possible cause. Müller prescribes diet deficient in cholesterol and thyroid tablets for his patients, without to date having been able to form any certain idea as to the effect, and thinks that this treatment may also conceivably be of prophylactic value for the predisposed but not yet affected members of xanthomatous families.

ANOMALIES OF THE LUMBOSACRAL ARTICULATIONS

CHAIRMAN'S ADDRESS

RAYMOND G. TAYLOR, M.D.

LOS ANGELES

The fifth lumbar vertebra shows more anomalies than any other vertebra in the body. The commonest ones have to do with the transverse processes and the articulations.

The transverse processes show a great variety in structure. They may be short, almost rudimentary, long and slender, or broad and massive. The latter, in varying degree, constitute one of the most common anomalies. The transverse process and the whole lateral mass may articulate with the sacrum (so-called sacralization of the fifth) or may be actually fused with the sacrum. This may be either unilateral or bilateral.

Roentgenograms of the lumbosacral region, made in the usual anteroposterior and lateral projections, show in some cases the fifth lumbar joints in a fairly satisfactory manner. In others no joint detail can be seen. The difference in structure of the joints of different patients is the reason for the difference in the radiographic appearance.

The articular facets are normally crescentic and the superior pair is slightly hollowed out and cuplike, the surface of the inferior facets being slightly convex to fit into the concavity of the facets of the vertebra below; normally they face laterally and slightly obliquely, the anterior borders of the joint surfaces being slightly closer together than the posterior borders. This results in the superior pair of articulations forming a converging aperture or space into which fits the inferior set of articulations on the vertebra above as a wedge. The weight on the vertebra above naturally shifts this vertebra forward as well as downward and tightens the wedge, narrowing the joint spaces and limiting side motion. The lumbar vertebrae in most backs will follow this pattern, with the exception of the fifth lumbar. The superior pair of joints of the fifth are generally of this type, but the inferior pair that articulate with the sacrum show wide variation in the direction the joint faces.

There are two main variations and they are relatively frequent. In addition to the conditions described, which one may say are approximately normal and give a stable back, each pair may face directly anteroposteriorly. The weight of the body above on the superior pair

then causes the joints to approximate and limits forward motion, but lateral motion is limited only by the integrity of the soft tissues, joint capsules, ligaments and muscles.

A second variation, not so common as the other, shows the joint faces resting directly one above the other, facing in a caudad-cephalad direction. This is the more unstable, of course, as there is no bony limitation in any direction.

Then there may be a combination of any of these three types of joints. A combination of any of these, with the lateral oblique on one side and either the anteroposterior or the caudad-cephalad on the other, results from a mechanical standpoint in a type of structure that is obviously unsuitable for certain types of motion and strain and the integrity of which necessarily depends not only on the bony structure but largely on the soft tissues, ligaments, joint capsules and muscles.

While it is true that the routine anteroposterior and lateral roentgenograms of the lumbosacral region may give very little actual information as to the condition of the joints, they do give one a good idea as to their abnormal facing. If these joints face laterally in the sagittal plane or slightly obliquely, a fairly good view through the joints can be had. If they face caudad-cephalad, which is rather uncommon but is seen occasionally, also a view through the joint may be had. If they face anteroposteriorly or in the coronal plane, of course no joint space is visible. This is true also if they are more than slightly oblique.

The width of the shadow on the roentgenogram of the articular process will give some idea as to the facing of the joints. When moderately oblique the processes will be moderately narrow, and when the joint surface is more nearly in the coronal plane they will be fairly broad.

So it seems reasonable to say that if one does not see through these joints in the routine type of anteroposterior roentgenogram they are abnormal as to their facing and that the wider the articular process shows in the roentgenogram the more nearly the joints face anteroposteriorly.

These deductions can be made from routine films but, to see through these joints and to learn something of their condition, lateral and oblique views must be made.

Abnormal motion in these joints does not always, but certainly may, result in damage to the joint or ligaments. As long as the joint capsule and conscious or unconscious muscular effort prevent abnormal movement, probably no damage occurs, but with the protection afforded by the soft tissues removed or inactive, abnormal motion is a definite menace and very likely to do damage to joint strictures or even trauma-

Read before the Section on Radiology at the Ninetieth Annual Session
of the American Medical Association, St. Louis, May 17, 1939.

tize the spinal nerves in some instances. Under ordinary conditions the movement in these joints is probably slight, but with the patient standing in an awkward position and placing too great a strain on these joints, or being caught off guard with relaxed muscles and subjected to sudden unexpected strain, enough movement is possible either to damage the synovia or to strain the ligaments, and he gets as a result an acute back pain varying in severity from mild continuous discomfort to sudden, sharp, shocklike pain, which may cause him

Fig. 1.—Normal facing of articular facets.

to drop in his tracks. With proper rest and the usual treatment the injured structures recover and pain subsides, leaving no trace so far as the roentgenogram is concerned. However, repeated damage to the same structure may sooner or later produce fibrous changes, scar tissue and in many instances calcium deposit in the injured tissues, which may then be definitely visible in the film.

There is some material in the literature regarding the anomalies of the fifth lumbar vertebra. Orthopedists are as a rule familiar with these conditions. Astonishingly enough, industrial surgeons and radiologists seem to give them scant consideration.

In 1920 Goldthwait¹ stated, in relation to back strain and pain, that an anatomic study usually indicates the reason for the pain. He enumerated various conditions due to anomalies, such as the transverse process of the fifth vertebra impinging on the sacrum or the spinous processes impinging on one another. He states that

Fig. 2.—Articular facets facing in coronal plane.

sacralization on one side results in a different degree of mobility on the two sides; that a crescentic or normal facet on one side and a flat one on the other will give different degrees of movement.

O'Reilly² in 1927 listed the abnormalities of the fifth lumbar vertebra, not mentioning the anomalies of facing in the facets but concluding from a study of 150 specimens of sacrum and fifth lumbar vertebrae that the articular processes show great variation in structure, and slipping might occur readily.

2. O'Reilly, A.: Abnormalities of the Lower Part of the Back, *J. A. M. A.* 89: 1128-1131 (Oct. 1) 1927.

In 1929 Willis,³ giving percentages of anomalies, gave none for the lumbosacral joints. At that time he thought that no definite normal had been determined for them but said that anomalies of structure and asymmetry suggest mechanical instability and susceptibility to ligamentous injury. They were of frequent occurrence and clinical importance.

Hubeny⁴ in 1931 described an oblique projection of the lumbar spine showing views through or between the joint facets. These, he suggested, showed arthritic deposits, effects of settling and impingement.

In 1932 Williams,⁵ in stressing the diagnostic importance of loss of or of thinning of the intervertebral disks, stated that the plane of the articular facets is undoubtedly a factor in determining the direction in which the subluxation (due to the thinning of the disks) which he describes takes place. He calls attention to the fact that the foramen of the fifth lumbar is smaller than those of the vertebrae above, and any decrease in size may produce compression symptoms in the nerve.

Brown⁶ in 1932 described in considerable detail the movement in these joints and stated that their anomalous development gives them a small factor of safety motion with a definite potential of injury.

Goldthwait⁷ in 1933 stated that muscular strains and fascial tears do occur but are rare and easily recognized.

Fig. 3.—Articular facets facing caudad and cephalad.

The chief problem deals with the mechanism of the joints. He described these joints as vertical, transverse, flat and crescentic. He stated that lumbosacral joint strains are by far the most common cause for backache.

Ghormley⁸ in 1933 stated that these are the only true joints of the spine, that the cartilage may undergo degeneration with eburnation of the underlying bone, accounting for the density and spur formation frequently seen in the roentgenogram. Injury to the facets can cause sciatic pain and lumbosacral pain with or without sciatic pain. He then called attention to the use of oblique views.

In 1934 the oblique view was elaborated on by Ghormley and Kirklin.⁹ They drew attention to the facts that the articulations make up a considerable portion of the margins of the intervertebral foramina. They regard these joints as true joints having perceptible motion. They believe that they have not been

sufficiently considered in the causation of back pain and that symptoms are more likely to be due to actual joint injury than to ligamentous strain or injury, although the latter is possible. Their belief is that the injury sets up muscular spasm, forcing the injured joint surfaces into contact, with increased pain. This may be followed by considerable swelling and effusion, which may encroach on the lumen of the intervertebral foramen, resulting in nerve pressure and its concomitant pain.

Brailsford¹⁰ in 1934 stated that the articular facets of the lumbosacral joints show great variability in their shape and in the plane of their articular surfaces. He evidently was not familiar with the oblique views, as he states that, if the facets face backward or are in the coronal plane, no idea of the condition of the surface of the joint can be obtained from a roentgenogram. He calls attention to the facts that the surfaces are generally vertical, but this is not always the case; that a considerable percentage of them are asymmetrical, and that the asymmetry favors abnormal movement which may cause strain on the ligaments.

Kimberley¹¹ in 1937 called attention to the fact that the lumbar vertebral articulations are in the sagittal plane, except at the fifth lumbar vertebra, where they may range from sagittal to coronal. He believes that the latter allow more rotation and lateral motion, as well as extension and flexion, but at the expense of stability. He thinks that it is rare to find a patient with low back pain who has symmetrical sagittal joints, and when asymmetry exists, movement on one side must be eccentric to the other, and trauma with synovitis and arthritis can readily be produced. The muscles attempt protection by going into tonic spasm, causing more fatigue and tenderness. A partial subluxation may take place with locking, which may account for cases in which there is sudden pain and perhaps a snap with also sudden relief, which may occur spontaneously or as a result of manipulation.

From these brief extracts from some of the articles in the American literature it should be fair to assume

the cause of the acute symptoms. If other causes, such as true infectious arthritis, synovitis, actual strain or rupture of fibers of the muscles of the back or actual fracture, are eliminated and anomalies of the joints are shown to be present, the latter are certainly in line for consideration as a potential cause of the injury and accompanying symptoms, especially when the history definitely connects the beginning of the symptoms with unusual strain, such as heavy lifting, violent muscular effort or a fall in an awkward position.

Fig. 5.—Combination of normal and caudad-cephalad facing of articular facets.

The commonest history one hears, of course, is that of heavy lifting by working men. It isn't possible, of course, to see the acute pathologic condition in the roentgenogram, but the mechanical setup for an injury of this kind can be observed and gives one a clue to its causation.

My purpose in calling attention to this matter is not that it is new but that I have been astonished to find that these anomalies are to a large extent ignored in radiologic reports. I have been observing these variations in the lumbar spine for a good many years and have been definitely calling attention to them in my radiologic reports for at least fifteen years.

It is obvious that most persons who have backs showing these anomalies are rather unsuited to hard manual labor such as lifting and straining. That they are more liable to injury than others with normal articular facets would seem reasonable. Any one who does a large volume of industrial work in which routine examinations of the lower part of the back in patients suffering from back strain are made will at once be struck by the large number of patients showing these anomalies. It would seem obvious that radiologic reports should call attention to these conditions.

1212 Shatto Street.

Fig. 4.—Combination of normal and coronal facing of articular facets.

that anomalies of the joints are common, that they give improper support to the body structures and are deficient in their weight bearing and strain resisting properties, and that the defects or anomalies allow damage to the joints and to their soft tissue supports, thereby being a fairly common and important cause of pain.

The majority of these backs show no marked pathologic changes of the bones. However, when abnormalities are present—and with good roentgenograms they can be seen and recognized—one has a possible clue to

Prevalence of Mental Disease.—On Jan. 1, 1935, there were approximately 450,000 patients resident in the mental hospitals of the United States. During that year an additional 140,000 were admitted, so that a total of about 590,000 were resident in mental hospitals at some time during 1935. To express these figures in terms of the general population means that at any given time during the year about one out of every 200 adults in the general population was a resident in a mental hospital, while one out of every 150 was under care at some time during the year. For New York State and Massachusetts, where hospital facilities are more adequate than in other states, one out of 150 adults in the general adult population was a resident patient at any given time during 1936 and almost one out of every 100 adults was under care at some time during 1936. These figures represent minimum estimates, since they are based only on the hospitalized insane; not included in these figures are those mentally ill patients who are in general hospitals, homes for the aged, and so on.—Landis, Carney, and Page, James D.: *Modern Society and Mental Disease*, New York, Farrar & Rinehart, Inc., 1938.

BROMIDE INTOXICATION

REPORT OF FIFTEEN CASES

LEWIS P. GUNDRY, M.D.

BALTIMORE

In recent years bromide intoxication has become a relatively common condition. Hanes and Yates¹ reported 400 cases which occurred at Duke Hospital in six and one half years. Wagner and Bunbury² examined the blood of 1,000 consecutive patients admitted to the Colorado Psychopathic Hospital and found bromide in the serum of seventy-seven. Many reports have come from all parts of this country. However, physicians still frequently fail to recognize the rather typical toxic states produced by bromide. It therefore seemed of interest to discuss again the cause, symptoms, diagnosis, prognosis and treatment of bromide intoxication and to report fifteen additional cases. Only those patients were included who had an initial blood bromide content above 150 mg. per hundred cubic centimeters.

To determine the blood bromide content the method of Wuth³ was used:

Ten cc. of blood was drawn from the vein and allowed to coagulate. To 4 cc. of the serum, 8 cc. of distilled water and 2.4 cc. of a 20 per cent solution of trichloroacetic acid were added. This mixture was shaken well, allowed to stand for thirty minutes and then filtered. To 6 cc. of the filtrate 1.2 cc. of a 5 per cent solution of gold chloride (Merck) was added, and a comparison was made on a colorimeter with a freshly prepared standard which contained either 100 mg. or 250 mg. of sodium bromide per hundred cubic centimeters.

All blood bromide levels given in the subsequent discussion are in milligrams of sodium bromide per hundred cubic centimeters of serum.

ETIOLOGY

When bromide is ingested it is eliminated rather slowly. Because bromide is less readily eliminated by the kidneys than chloride there is a tendency for it to accumulate in harmful amounts. Furthermore, since the output of bromide is increased by the ingestion of chloride, intoxication will occur more readily when the intake of chloride is restricted. This fact is illustrated clearly by an early case cited by Hashinger and Underwood:⁴ a druggist's servant filled the salt cellars with sodium bromide, and a toxic psychosis developed in every member of the family.

Bromide intoxication has been encountered most often in patients with a psychoneurosis, a psychosis, chronic alcoholism, cerebral arteriosclerosis, brain tumor or other organic disease. The patients commonly complain of headache, nervousness or symptoms of insomnia, for which the average physician prescribes bromides with alarming frequency. It is not surprising therefore that physicians' prescriptions have

caused approximately 50 per cent of the reported cases of bromide intoxication. Repeated refilling of a prescription which calls for a moderate dose of bromide may eventually result in poisoning. On the other hand, the patient may totally disregard instructions and take large frequent doses:

CASE 1.—A young man who had been drinking heavily went to his physician for treatment. The physician prescribed bromide in a dose of 15 grains (1 Gm.) four times daily, but the patient took at least twice this amount. There developed a severe intoxication, which necessitated hospitalization.

The patient with chronic alcoholism is particularly prone to develop bromide poisoning, since he has a low chloride intake and in addition is usually dehydrated. Furthermore, it is a well known fact that such patients frequently take excessive doses of any medication. Several patients in this series literally substituted bromide solutions for alcohol at the end of a spree:

CASE 2.—A garage mechanic aged 42 after a spree of several months' duration found himself in the custody of a friend who was a strict prohibitionist. He promptly shifted from whisky to a prescription which contained bromide, and after he had consumed several bottles of this in a few days had moderately severe intoxication with mental symptoms which made hospital treatment imperative.

Several similar cases were encountered in this series, in all of which the intoxication developed rapidly as a result of large doses. Cross⁵ has warned of the danger of prescribing bromides for the patient with chronic alcoholism. In my opinion bromide should never be prescribed in the treatment of chronic alcoholism unless the patient is kept under close observation and the drug administered either by a nurse or by some equally responsible person.

Frequent references were found in the literature to cases in which bromide poisoning resulted from proprietary medicines. Such medicines, used indiscriminately, caused the intoxication in two of the cases here reported:

CASE 3.—A woman aged 71 had taken several doses of bromo-seltzer daily for at least ten years. She became ill, with many paranoid hallucinations. The blood bromide content was 212 mg.

CASE 4.—A young married woman took 30 ounces (900 cc.) of neurosine in five days. There rapidly developed a severe toxic psychosis, from which she recovered in three weeks.

Anemia and arteriosclerosis are repeatedly mentioned as contributory causes. The patient who took bromo-seltzer had advanced arteriosclerosis. Patient 13 (table 1) showed marked arteriosclerosis, to which her slow recovery was largely attributed. In the case which follows anemia was a prominent feature:

CASE 5.—A druggist aged 57 had insomnia and had taken uncertain doses of bromide for one year. On admission to the University Hospital he was drowsy, pale and confused mentally. The blood bromide content was 413 mg., the hemoglobin content was 66 per cent and the red cells numbered 3,680,000. He made a satisfactory recovery in four weeks. The anemia apparently arose from an inadequate diet.

Finally, it is well known that the state of bodily health may determine whether or not intoxication will occur in a given instance. Barbour⁶ gave large doses

of bromide to six healthy controls with no ill effect. All the patients discussed in this paper were in poor health.

In nine of the fifteen cases here reported (table 1), bromides were prescribed by physicians. In two instances the patient had taken a proprietary medicine. Chronic alcoholism was the underlying condition in eight cases; in one of these there was also a psychosis. Psychoses (one toxic and one with cerebral arteriosclerosis) were present in two others; in two there was a psychoneurosis. The remaining three were cases of anemia, eczema and brain tumor, respectively. The last-

has pointed out, the mental symptoms are colored by the personality of the patient. For example, the patient with dementia praecox and bromide intoxication would still have psychotic symptoms when there was not a trace of bromide in his blood. Delirium has been noted at a much lower concentration of blood bromide in the high-strung unstable person than in the normal person. This fact is well illustrated by the following case:

CASE 7.—A salesman aged 59 had been peculiar, with many functional symptoms, for years. Under stress of family difficulties he took large doses of bromide and reacted with a confused, semidelirious, paranoid mental state. The blood bromide

TABLE 1.—Fifteen Cases of Bromide Intoxication

Case	Sex	Age, Yr.	Source of Bromide	Underlying Condition	Level of Sodium Bromide in Serum on Admission, Mg./100 Cc.	Physical and Neurologic Signs	Length of Stay in Hospital, Result
1	♂	31	Physician's prescription	Chronic alcoholism	454	Speech thick and incoherent, pupils inactive to light, tongue coated, reflexes not elicited, broad base gait	28 days; cured
2	♂	42	Self medication	Chronic alcoholism	295	Thick speech, coated tongue, weak legs, diminished knee jerks, very poor coordination, unsteady gait	21 days; cured
3	♀	71	Self medication, bromo-seltzer	Senile psychosis, generalized arteriosclerosis	212	Dusky cyanosis, coated tongue, large heart, generalized arteriosclerosis	Cured of bromism, psychosis remained
4	♀	32	Physician's prescription, acuosine	Chronic alcoholism	357	Coated tongue, hyperactive knee jerks, poor coordination, unsteady broad base gait	22 days; cured
5	♂	57	Self medication	Anemia	415	Pale mucous membranes, thick speech, coated tongue, rash on forearms, diminished knee jerks	24 days; cured
6	♂	58	Physician's prescription	Headaches, brain tumor	350	Thick speech, sordes, retinal arteriosclerosis, hyperactive reflexes	13 days, improved; died several months later of brain tumor
7	♂	55	Self medication	Psychoneurosis, bronchial asthma	182	Coated tongue, malnutrition, musical rales at bases of lungs	No marked change; transferred
8	♀	35	Physician's prescription, bromide and chloral	Chronic alcoholism	715	Speech thick, dehydrated pupils sluggish to light, tongue coated, tachycardia, legs very weak, coordination very poor	Cured, 3-4 weeks (no more data)
9	♂	35	Physician's prescription	Chronic alcoholism	223	Maculopapular eruption, coated tongue, large liver, absent knee jerks, poor coordination, unsteady gait	5 days; cured
10	♂	34	Self medication, triple bromides	Chronic alcoholism plus psychosis	398	Thick speech, pupils inactive to light, coated tongue, rales at bases of lungs, absent knee jerks, poor coordination	Recovered from psychosis, 11 months
11	♀	40	Self medication	Chronic alcoholism, essential hypertension	500	Thick incoherent speech, dirty teeth, coated tongue, reddish macular skin lesions, tachycardia, rales at bases of lungs, very poor coordination, unsteady broad base gait	42 days; cured
12	♀	45	Physician's prescription	Chronic alcoholism	186	Thick speech, eruption on back and neck, coated tongue, diminished knee jerks, ataxic broad base gait	10 days; cured
13	♀	74	Physician's prescription	Diabetes, eczema with pruritus	500	Thick speech, puffed face, generalized eruption, rales at bases of lungs, coarse tremor, overactive knee jerks	34 days; cured
14	♀	21	Physician's prescription	Psychosis	168	Heavily coated tongue, poor coordination	Cured; recovered from psychosis, 5 months
15	♀	41	Physician's prescription	Psychoneurosis	555	Thick speech, masklike face, weak legs, ataxia coarse tremor	15 days, recovered, at home

mentioned case was of special interest because the seriousness of the underlying condition was not recognized during the period of treatment for bromism:

CASE 6.—A man aged 58 had complained of headaches for several months. On admission he showed thick speech, unsteady gait and a blood bromide content of 350 mg. Neurologic examination gave no evidence of a localized lesion. An examination of the fundi, a roentgenogram of the skull and a spinal puncture gave no positive information. He improved but was not well on discharge from the hospital. There was no further improvement, and after a few months bilateral choking of the disks developed. An exploratory craniotomy revealed a brain tumor. The patient was comatose at this time and died a few days later.

SYMPTOMS

In any discussion of the symptoms of bromide intoxication it must be remembered that these symptoms are usually superimposed on those of an underlying neuropsychiatric or organic physical condition. As Diethelm⁷

content was 182 mg. In spite of the mild nature of the intoxication, recovery was slow.

Headache, anorexia, dizziness, tremors, fatigue, irritability, poor memory and transitory mental confusion have been noted frequently as early symptoms. Several of these symptoms were usually found in cases in which there was a blood bromide content between 50 and 150 mg. Mental manifestations were either evanescent or entirely lacking in such mild intoxications.

If the bromide medication was continued or (as often happened) the dose was increased in an attempt to overcome the symptoms of mild intoxication, restlessness, weakness, thick speech and unsteady gait became clinical features. Patients were fearful and anxious, with frequent emotional outbursts. There were aural and visual delusions and hallucinations. In some cases delirium was a feature, although Curran⁸

7. Diethelm, Oskar: On Bromide Intoxication, *J. Nerv. & Ment. Dis.* 71: 151 (Feb.), 278 (March) 1930.

8. Curran, Frank J.: A Study of Fifty Cases of Bromide Psychosis, *J. Nerv. & Ment. Dis.* 88: 163 (Aug.) 1938.

reported that pure delirium was rare. Such symptoms usually occurred with a blood bromide content of from 150 to 250 mg.

When the blood bromide content exceeded 250 mg., the clinical picture was dominated by the symptoms characteristic of a toxic psychosis. The patient was often uncooperative, noisy and even actively combative. The mood varied from elation to abject fear or terror. The speech was usually thick and jumbled; it was slurred to such an extent as to be almost unintelligible in some cases. There were many delusions and hallucinations; the patient frequently carried on confused conversations with imaginary persons on the ceiling or saw large men and animals of all descriptions. He frequently believed that he was to be executed or that some members of his family had been killed. Complete disorientation was often observed, and defective

of fifteen cases. These maculopapular lesions were in no way proportionate to the severity of the intoxication; such eruptions were considered by Bailey¹⁰ to be an allergic manifestation.

Neurologic signs which have been considered important are thick slurring speech, sluggish pupillary response to light, decreased or increased tendon reflexes, broad base gait and gross lack of coordination. Of these the slurring speech, broad base gait and ataxia were most characteristic in this series. The degree of ataxia was roughly proportionate to the severity of the intoxication:

CASE 8.—A woman aged 35 had been drinking heavily and had taken large doses of bromide prescribed by her physician over a period of three weeks. She exhibited the most marked ataxia and often missed by several feet objects she attempted to touch. The blood bromide content was 715 mg.

TABLE 2.—Relation of Blood Bromide Content to Mental Status

Case	Sodium Bromide in Serum on Admission, Mg./100 Cc.	Mental Status	Sodium Bromide in Serum		Mental Status at That Date
			Mg./100 Cc.	No. of Days Later	
1	454	Combative, suspicious, fearful, hallucinated, semistuporous, delirious	135	11	Practically normal
2	295	Combative, anxious, fearful, hallucinated, lethargic, delirious	105	14	Normal
4	357	Confused, fearful, hallucinated, confabulatory, drowsy	158	8	Normal
5	413	Confused, dull, irritable, hallucinated, lethargic	133	14	Normal
6	350	Confused, hallucinated, disoriented	200	13	Still confused at times
10	398	Combative, suspicious, fearful, hallucinated, delirious	133	14	Underlying psychosis, no toxic symptoms
11	500	Confused, anxious, fearful, hallucinated, semistuporous, delirious	85	19	Normal
12	196	Confused, antagonistic, mildly delirious	125	5	Normal
13	500	Confused, suspicious, fearful, hallucinated, drowsy	100	33	Normal
15	555	Confused, suspicious, fearful, hallucinated, semistuporous	244	14	Still confused

memory with a tendency to confabulation was noted in several instances. In cases of such severe intoxication there was usually a lethargic or semicomatose state. As noted, delirium was at times a feature. Coma such as that which occurred in the case reported by Craven and Lancaster⁹ was not encountered in this series. When the patient was comatose or semicomatose, death most commonly resulted from pneumonia. It is noteworthy in this connection that patients 10 and 11, with high initial blood bromide levels, showed congestive changes at the bases of their lungs on admission.

Low grade fever, masked facies, sordes, coated tongue, tachycardia, decreased systolic blood pressure and weakness in the lower extremities have been noted as the most prominent physical signs. In the patient with chronic alcoholism hepatic enlargement was frequently found. The associated acne-like cutaneous lesions, which have been greatly overemphasized, were not common in this series; they occurred in only four

It has been my experience that the clinical picture with particular reference to the mental status closely parallels the level of bromide in the blood. When this level did not exceed 150 mg., there were usually no definite symptoms of intoxication. Above this level there were in most cases symptoms which became more pronounced as the concentration of bromide increased. Furthermore, under treatment these symptoms regressed; the patient was usually mentally clear when the blood bromide level had fallen below 150 mg. A casual study of table 2, which shows the relation of the blood bromide level to the mental status in this series, will serve to substantiate these statements.

DIAGNOSIS

In the diagnosis of bromide intoxication the history was not of much assistance. The patient was frequently unable to give accurate information, and the family or friends did not know about such details. However, pharmacists and other physicians proved most helpful when the question of previous medication arose.

The diagnosis then must be made mainly on the symptoms and physical signs discussed. When a patient with a toxic mental condition characterized by fearful hallucinations, disorientation and delirium is encountered, bromism must be considered as a possible diagnosis. If in addition he shows thick speech, coated tongue, broad base gait and lack of coordination, bromide poisoning should be diagnosed clinically.

As Hanes and Yates¹ have pointed out, the blood bromide determination "is an absolutely indispensable aid" in confirmation of the diagnosis. Such a determination should be done as a routine in any case of a toxic, confused mental state or in any case of coma of unexplained origin. In cases of severe bromide intoxication this test should be repeated at frequent intervals to determine the results of treatment.

The neurologic picture in bromide intoxication when accompanied by fever and a lethargic mental state makes differentiation from encephalitis a difficult problem. Syphilis of the central nervous system also offers great difficulty at times. These two conditions can be ruled out only by blood bromide determination and careful study of the spinal fluid. In cases of chronic alcoholism differentiation must be made from alcoholic hallucinosis, delirium tremens and Korsakoff's syndrome. Thick speech and poor coordination are not usually features of these alcoholic mental states.

9. Craven, E. B., Jr., and Lancaster, Forrest J.: Coma Due to Bromide Intoxication, J. A. M. A. 106:1383 (April 18) 1936.

10. Bailey, R. J.: Bromoderma, Proc. Staff Meet., Mayo Clin. 11: 630 (Sept. 30) 1936.

Furthermore, there is no evidence of neuritis in cases of bromism. Finally, in cases of semicoma or coma, poisoning from barbitol or some other hypnotic must be ruled out. Clinically, recovery from poisoning by bromide is much slower than that from poisoning by any of the other sedatives. However, since prompt diagnosis is important in such cases, determination of the blood bromide offers the only speedy solution of the problem.

PROGNOSIS

The mortality from bromide intoxication per se is very low. In the many hundreds of cases which have been reported in recent years, only seven fatalities have been noted; this constitutes a mortality well under 1 per cent. Most of these deaths occurred in instances of severe intoxication complicated by pneumonia. In the series here reported there were no deaths from bromism, but patient 2 has since died of chronic alcoholism and patient 6 of brain tumor.

Recovery from the symptoms of bromide poisoning requires from one to six weeks, depending largely on the severity of the intoxication. It is noteworthy, however, that an underlying psychosis was found in three of the cases here discussed and that there has been a recurrence of drinking in several of the cases of chronic alcoholism. The ultimate prognosis should therefore be reserved until the toxic symptoms have entirely abated and the underlying mental and physical condition has been carefully appraised.

TREATMENT

Preventive.—In approximately half of the cases, bromide intoxication results from physicians' prescriptions. It is therefore obvious that physicians can play a very important part in the prevention of bromism. Before bromide is prescribed the physician should be sure that the patient is getting none of this drug from other sources. Prescriptions should be marked "not to be refilled." The intake of sodium chloride should be adequate at all times. At subsequent visits the patient should be questioned concerning symptoms of mild intoxication before bromide medication is continued. Whenever doubt arises concerning intoxication the blood bromide should be determined. Finally, the public in general and physicians in particular should be educated concerning the danger inherent in self administration of bromide or of the many proprietary medicines which contain bromide.

CURATIVE

Because chloride replaces bromide in the body and promotes its elimination by the kidneys, sodium chloride is a specific in the curative treatment of bromide intoxication. This inexpensive medication is most easily given by mouth in capsules. The dose recommended by most authors is from 4 to 10 Gm. daily; this dose was found effective in the fifteen cases reported here. It was necessary to give sodium chloride intravenously to only one patient, he having refused to take salt by mouth. There was a temporary increase in mental symptoms in three of the fifteen cases when sodium chloride was first given. This phenomenon is probably explained by increased elimination of bromide from the tissues, which exceeds renal elimination, with a resultant temporary rise in the level of blood bromide. Because of this paradoxical possibility, Wagner and Bunbury² advised that sodium chloride be withheld at first in

cases of severe intoxication. An interesting observation in this series was the excellent cooperation of the patients in taking the sodium chloride capsules. They seemed quickly to realize that the capsules helped them, and it was not unusual for a semidelirious patient to demand his capsules if the nurse did not administer them promptly.

Important supportive treatment consists of the forcing of at least 4,000 cc. of fluids daily, a nutritious soft diet and good nursing care. It is undesirable to restrain the patient by mechanical means, since he is thus made more fearful and restless. In addition the danger of pneumonia is greatly increased by confining the patient to bed. He is much more easily handled if he is placed in a warm room with a minimum of furniture. Special nursing is desirable in cases of severe intoxication.

The question of sedatives is an important one; the patient is most restless at times and becomes exhausted if he does not obtain sufficient sleep. Paraldehyde was used almost exclusively in the present series of cases, with very satisfactory results. The dose used was from 4 to 16 cc. given by mouth or from 12 to 24 cc. given by rectum. Phenobarbital and seconal¹¹ were used sparingly to reinforce the paraldehyde when necessary.

SUMMARY

1. Bromide intoxication is a common condition, and, judging from the hundreds of cases which have been reported, it is prevalent in all parts of this country.

2. In spite of its prevalence, many physicians still fail to recognize this condition.

3. The cause of bromide intoxication is most commonly a physician's prescription written for an alcoholic addict, a psychoneurotic person or a psychotic patient. If the chloride intake is low or if the patient is suffering from some debilitating disease, intoxication occurs more readily.

4. The severity of the symptoms of bromism closely parallel the elevation of the blood bromide level. These symptoms are characteristic and are found to some degree in all patients with a blood bromide content above 150 mg. per hundred cubic centimeters.

5. An alert physician should be able to make the diagnosis from the history and physical examination. The blood bromide determination confirms the diagnosis.

6. The prognosis should be guarded until the underlying condition has been studied.

7. Treatment of bromide intoxication is divided into preventive and curative. The latter is easy and satisfactory, but the former is more important for the physician to remember.

1014 St. Paul Street.

ABSTRACT OF DISCUSSION

DR. C. C. UNDERWOOD, Emporia, Kan.: Bromide intoxication should be of interest to all physicians regardless of their specialty. Fortunately the determination of the blood bromides is relatively simple and may be done in any laboratory possessing a colorimeter, so that the suspected diagnosis of a toxic bromide state is easily confirmed or disproved. A determination of the blood bromides should always be made whenever nervous patients seem to grow worse after taking bromides for a time or else medication should be immediately stopped. In 1934 and 1935 Hashinger and I, thinking it possible that bromide determination on the spinal fluid might be a more

11. The sodium salt of propyl-methyl-carbinyl allyl barbituric acid or sodium allyl (1-methylbutyl) barbiturate.

sensitive indication of the patient's mental state, made a small number of such determinations. The spinal fluid bromide levels were usually a little less than half those of the blood bromides. The spinal fluid determinations therefore cannot be considered superior to those of the blood serum in making the diagnosis or prognosis. Twelve patients with bromide intoxication have been admitted to University of Kansas hospitals since the publication of our paper. These cases seem to show the peculiar susceptibility of cardiac and cardiorenal patients and the fact that there seems to be an idiosyncrasy on the part of certain people, some having a complete symptom complex from low concentration and others being utterly free of any symptoms from a high concentration of bromides in the blood. One of our most severely affected patients was a young married woman who had acute nephritis and was instructed to avoid meat and salt. She was given a salt substitute containing sodium bromide. There is nothing to add to the method of treatment as outlined by Dr. Gundry. I wish to emphasize the fact brought out in Dr. Gundry's paper that the patient with bromide intoxication is usually ill before the administration of bromides and that the clinician should be careful not to overlook a more serious malady after the diagnosis of bromide intoxication is established.

DR. ELMER L. DE GOWIN, Iowa City: Dr. Gundry stated that cutaneous manifestations were not common in patients with bromide intoxication. I wish to elaborate on this observation. Dr. L. W. Kimberly of the Department of Dermatology of the State University of Iowa has allowed me to summarize the results of some unpublished studies he made on this point. Of thirteen patients with acute bromism and mental symptoms, with plasma bromides between 57 and 562 mg. per hundred cubic centimeters, only one had cutaneous manifestations. A study of sixteen patients with bromoderma in whom the blood bromides were in general lower revealed no correlation between the level of bromides in the blood and the occurrence of the cutaneous lesions. Occasionally the bromoderma disappeared while the bromide level of the blood was still high. He then attempted to produce bromoderma by giving patients bromides by mouth. In a group of four patients who had previously had bromoderma, the cutaneous manifestations recurred in all when the blood bromide levels were relatively low. When ten patients who had never had bromide eruptions were fed bromides, no cutaneous manifestations could be produced although the blood bromide levels were higher than in the group with bromoderma and two patients became temporarily disoriented. From these data Kimberly concluded that the cutaneous manifestations are the result of idiosyncrasy to the drug. When patients had a constant intake of sodium chloride and sodium bromide, great individual variation in the bromide levels of the blood resulted. Ingestion of 1 Gm. of sodium bromide produced plasma bromide levels from 0.46 mg. to 5.8 mg. per hundred cubic centimeters in different individuals. The effect of the administration of sodium chloride on the blood bromide level also was studied. It was found that the daily injection of 200 cc. of 2 per cent sodium chloride intravenously produced a more rapid fall in blood bromides than did the oral administration of salt.

DR. LEWIS P. GUNDY, Baltimore: The point Dr. Underwood brought out is a very good one, that all physicians in all types of practice will see these patients with bromide intoxication. Of the fifteen cases here reported, most of them were seen by general practitioners; a good many of them were produced by general practitioners. Dr. De Gowin stressed the scarcity of cutaneous lesions. That was borne out by the cases reported here. He also mentioned the fact that there is no relation of the blood bromide level to cutaneous manifestations. The patient in this series who had 715 mg. of sodium bromide per hundred cubic centimeters had no trace of a cutaneous lesion. Others whom I have seen with blood bromides of 100 and 120, ordinarily not considered toxic levels, had a rather marked acne-like eruption characteristic of bromide, sometimes called a bromide rash. Also there are great individual differences in patients in their susceptibility to bromide intoxication. I would again stress the point that at least 50 per cent of these cases are caused by physicians' prescriptions. I think we should continue to use bromides, but I think we should use them with considerably more caution than has been the case in the past.

VARIOUS COMPLEMENTARY FEEDINGS USED DURING THE NEONATAL PERIOD

EFFECT ON THE GAIN IN WEIGHT AND THE
STIMULATION OF BREAST MILK

HEYWORTH N. SANFORD, M.D.

CHICAGO

The problem of adequate feeding for the infant during the neonatal period has been discussed for many years. The fact that almost every hospital has a different procedure gives the impression that perhaps the various feedings may not be of such importance as one has been led to believe, i. e. that the newborn infant adjusts itself to its new environment after a certain period no matter what is done or, one might say, in spite of outside interference. To obtain an idea of the effect of various feedings, the following study was carried out.

PROCEDURE

This study was begun in January 1930 and involves the records of 4,622 infants. The newborn infant is under the supervision of the pediatric department as soon as it enters the nursery. A daily chart is kept

Birth Weight of Infants Studied

Year	Total No. of In- fants	5 to 6 Lb.		6 to 7 Lb.		7 to 8 Lb.		8 to 9 Lb.		9 to 10 Lb.		10 to 11 Lb.

of its weight, the food intake and the water intake. These intakes are charted separately for each feeding. When the baby is sent to breast, as it is within the first twenty-four hours in all instances, weighing before and after nursing gives the exact amount of breast milk obtained. For the first seven years of the study all the babies were fed or sent to breast six times in twenty-four hours, i. e., at four hour intervals. For the last two years they were fed and sent to breast only five times in twenty-four hours, i. e. the 2 a. m. feeding was omitted. In the first five years of the study, in which various complementary feedings were given, the infant was first sent to breast and the amount obtained was subtracted from the calculated requirement for the infant (3 ounces of fluid complement per pound in twenty-four hours). The required complementary feeding was then given, each infant being allowed to take as much as it would of the calculated feeding.

The various complementary feedings were given for a period of one year. Five per cent of carbohydrate was used with each feeding to standardize the study. No complementary feeding was used in the last four

years, during which two year periods were employed. The feedings were as follows:

- 1930. Protein Milk. The nonboilable milk in the proportion of 1 tablespoonful of protein milk to 2 ounces of water, with 5 per cent of carbohydrate (dextrimaltose No. 1).
- 1931. Lactic Acid Milk. Cow's whole milk, fresh, boiled five minutes, acidified with lactic acid, 3 drops to the ounce of milk, with 5 per cent of carbohydrate (dextrimaltose).
- 1932. Two thirds cow's milk, fresh, boiled five minutes; one third boiled water, and 5 per cent carbohydrate (cane sugar).
- 1933. One half cow's milk, fresh, boiled five minutes; one half boiled water, and 5 per cent carbohydrate (cane sugar).
- 1934. Five per cent dextrose solution.
- 1935 and 1936. No complementary feedings. Boiled water every four hours alternate to breast feedings, as much as the infant would take; six breast feedings in twenty-four hours.
- 1937 and 1938. Feedings as in 1935 and 1936, but only five breast feedings in twenty-four hours (2 a. m. feeding omitted).

RESULTS

The accompanying table shows the sex and birth weight of the babies, together with the average weights. The loss of weight from birth was calculated for each baby from the lowest point in the weight curve in the ten day period. It was found that the easiest method of grouping these losses was by dividing them into percentage of loss as compared with birth weight. The results of the various complementary feedings are shown in chart 1, which comprises data on those infants for whom the loss of weight was 5 per cent of the birth weight or less.

Chart 2 enumerates those infants for whom the loss of weight was between 5 and 8 per cent of the birth weight; chart 3, those infants for whom the loss of weight was between 8 and 10 per cent of the birth weight, and chart 4, those infants for whom the loss of weight was 10 per cent or more of the birth weight. The gain in weight after the initial loss was calculated for each baby. It was found that the easiest method of showing this gain was to compare the weight at the

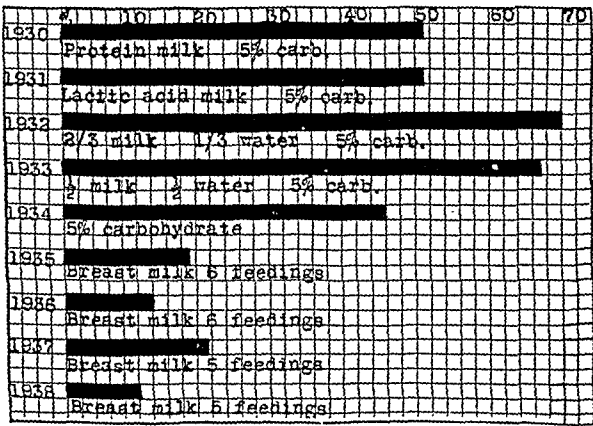

Chart 1.—Loss of weight; percentage of infants who lost less than 5 per cent of their birth weight

age of 10 days with the weight at birth. Chart 5 enumerates by yearly periods all the babies who regained or exceeded their birth weight in the ten day period. The effect of the various feedings and procedures on the secretion and stimulation of breast milk was calculated by comparing the calories or ounces of breast milk received with the weight of the baby. This amount

was calculated on the tenth day. Chart 6 enumerates those infants who received no breast milk at the end of the ten day period. Chart 7 lists those who received less than 25 calories (1¼ ounces) per pound in twenty-four hours. It is assumed that the caloric value of all breast milk is 20 calories per ounce. Chart 8 enumerates

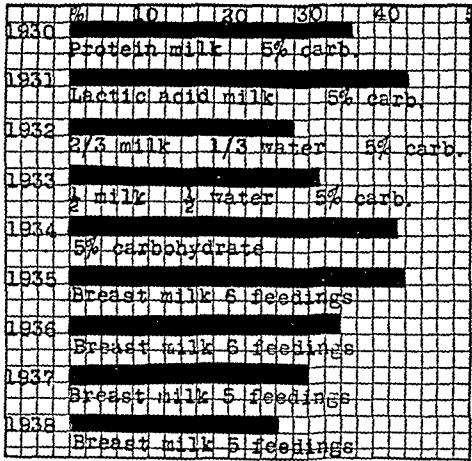

Chart 2.—Loss of weight; percentage of infants who lost between 5 and 8 per cent of their birth weight.

those infants who received from 25 to 35 calories (1¼ to 1¾ ounces) per pound; chart 9, those who received from 35 to 50 calories (1¾ to 2½ ounces) per pound, and chart 10, those who received 50 calories (2½ ounces) or more per pound.

COMMENT

An examination of the table will show that year for year there was little difference in the average birth weights of the babies. Thirty-eight per cent of the babies weighed between 7 and 8 pounds (3,175 and 3,628 Gm.), 24 per cent weighed between 6 and 7 pounds (2,721 and 3,175 Gm.) and 24 per cent weighed between 8 and 9 pounds (3,629 and 4,082 Gm.). Six per cent weighed between 5 and 6 pounds (2,268 and 2,721 Gm.), and 7 per cent weighed between 9 and 10 pounds (4,082 and 4,536 Gm.). Only 0.9 per cent weighed between 10 and 11 pounds (4,536 and 4,989 Gm.). Premature infants were not included in this study. One can assume from these yearly averages of weights that, on the whole, this was an average group of newborn infants.

LOSS OF WEIGHT

The physiologic loss of weight of the newborn has been a subject of discussion for many years. Certainly it is normal for nature. However, there has been a tendency in the last few years to attempt to improve on nature and prevent this loss of weight. In the four charts showing loss of weight the infants are divided into groups having lost less than 5 per cent of the birth weight, between 5 and 8 per cent of the birth weight, between 8 and 10 per cent of the birth weight and more than 10 per cent of the birth weight. In using a complementary feeding, as might be expected a loss from the birth weight of 5 per cent or less was observed for more than one half of the babies (except in the case of 5 per cent dextrose, with which the loss was a little less, 44 per cent). However, a high caloric content of the complement does not necessarily decrease the loss of birth weight. The complement of highest caloric value, lactic acid milk, prevented

a loss of birth weight of less than 5 per cent in only a few more of the babies than did the dextrose, with its low caloric value.

For preventing an excessive loss of weight from birth, the best results were obtained with a complement consisting of two thirds milk, one third water and 5 per cent carbohydrate, with which two thirds of the babies

Chart 3.—Loss of weight; percentage of infants who lost between 8 and 10 per cent of their birth weight.

lost less than 5 per cent of their birth weight. Again, it must be noted that even with this rich complement the loss was only 3 per cent less than with one half milk, one half water and 5 per cent carbohydrate. Without feedings complementary to their mother's milk, only 14 per cent, or about one seventh, of newborn babies will show a loss of weight from birth of less than 5 per cent.

An examination of the babies that lost between 5 per cent and 8 per cent of their birth weight (chart 2) shows a remarkable similarity for every form of feeding. The highest figure, 42 per cent, was exactly the same for the

Chart 4.—Loss of weight; percentage of infants who lost more than 10 per cent of their birth weight.

year in which lactic acid milk was used and one year in which no complement was given. There is only 16 per cent difference between the highest number and the lowest number. This indicates that loss of weight from birth in a certain number of babies is independent of complementary feeding or, in fact, any form of feeding. In other words, irrespective of what kind of feeding is given, approximately 33 per cent of all newborn

babies will lose from 5 to 8 per cent of their birth weight at their period of greatest loss.

Chart 3 shows that all babies will lose less if given a complementary feeding than if given nothing but their mother's milk. With the complementary feeding with which the greatest loss of weight occurred, protein milk, only one half as many babies lost between 8 and 10 per cent as in one of the years in which breast milk was given alone.

Finally, chart 4 shows that excessive loss, namely over 10 per cent, of the birth weight is rare in babies given any form of complementary feeding. The loss is practically the same for all milk preparations (1 and 2 per cent) and for simple 5 per cent dextrose and protein milk (only 3 per cent). The average for the two years in which no complement was given was 18 per cent for six feedings of breast milk in twenty-four hours and 25 per cent for five feedings in twenty-four hours. It may be said therefore that with no complementary feedings approximately one fourth to one sixth of newborn babies will lose more than 10 per cent of their birth weight.

From the results of these studies one may summarize loss of weight during the neonatal period as follows: Irrespective of whether or not a complement is used,

Chart 5.—Gain of weight; percentage of infants who had returned to or passed their birth weight by the tenth day.

approximately 33 per cent, or one third, of newborn babies will lose between 5 and 8 per cent of their birth weight. This one may assume is about the average loss of weight for the average newborn baby. The loss may be influenced by the feeding of a complement to the breast milk obtained and is to some extent proportional to the caloric value of the complement. The higher the caloric value of the complement the less the loss of birth weight. With ordinary complements, including even 5 per cent dextrose, about one half of newborn babies will lose only 5 per cent or less of their birth weight. With complements of high caloric value, this figure may be increased to two thirds. Conversely, it is exceptional for an infant receiving any form of complementary feeding to lose as much as 10 per cent of its birth weight, but with infants not given any complementary feeding who receive six nursings of breast milk in twenty-four hours one must expect that 18 per cent, or approximately one sixth, will lose 10 per cent or more of their birth weight. When only five nursings are received in twenty-four hours, one must expect 25 per cent, or one fourth, of the infants to lose 10 per cent or more of their birth weight.

GAIN IN WEIGHT

In the study of the gain of weight of the infants receiving various forms of feedings, while the gain in weight was calculated for each infant it was found necessary to have some standard of comparison. This was established by again comparing the gain to the birth weight. In chart 5 is tabulated the percentage of infants who had regained their birth weight by the tenth day of life. The caloric content of the complementary feeding seemed to affect the rapidity of the gain in weight. The greatest number of infants regained their birth weight with the heavier feedings. Fifty-seven per cent were found in the group given lactic acid milk and 5 per cent carbohydrate as a complement, although the group given two thirds milk and one third water with 5 per cent carbohydrate was close, with a figure of 54 per cent. Strangely enough, only 38 per cent of the group given one half milk and one half water with 5 per cent carbohydrate had regained their birth weight, while 41 per cent of the group given simply 5 per cent dextrose had done so. One can assume therefore that the rapidity of a return to birth weight is roughly proportional to the caloric content of the complementary feeding.

Chart 6.—Amount of breast milk; percentage of infants who received no breast milk.

Of the babies given no complementary feeding, 25 per cent of those given six and 14 per cent of those given five feedings of breast milk in twenty-four hours had returned to their birth weight. However, this is unfortunately a rather biased view of the situation. The breast-fed babies suffered a greater initial loss of weight than did those given a complementary feeding. Actually they gained faster but in ten days could not overcome the initial loss.

One may summarize the gain in weight of newborn infants as follows: About one half given a complementary feeding will have regained their birth weight within ten days. The rate of gain is influenced by the caloric content of the complementary feeding. The higher the caloric value the more this figure will exceed one half, and the lower the caloric value the less likely it is to reach one half. If newborn infants are given no complementary feeding but are nursed six times in twenty-four hours, one fourth will have regained their birth weight at the age of 10 days, and if they are nursed five times only one seventh will have regained this weight. However, this is due to the greater initial loss; actually the gain of weight is faster than in those given complementary feedings.

AMOUNT OF BREAST MILK

In the study of the amount of breast milk obtained by the infants given the various types of feeding, the infants were again divided into groups. Chart 6 shows the percentage who obtained no breast milk. The greatest number received a complement with a high caloric value and the smallest number a complement

Chart 7.—Amount of breast milk; percentage of infants who received less than 25 calories (1 1/4 ounces) per pound.

with a low caloric value. The number of those who received 5 per cent dextrose is not different from the number of those who received no complementary feeding. In both groups who were given mother's milk alone there appear to have been approximately 5 per cent of the babies whose mothers had no milk. When complementary feedings were given the number was doubled.

Chart 7 indicates that when the mother has less than the required amount of breast milk a complementary feeding may actually cause it to diminish. More infants

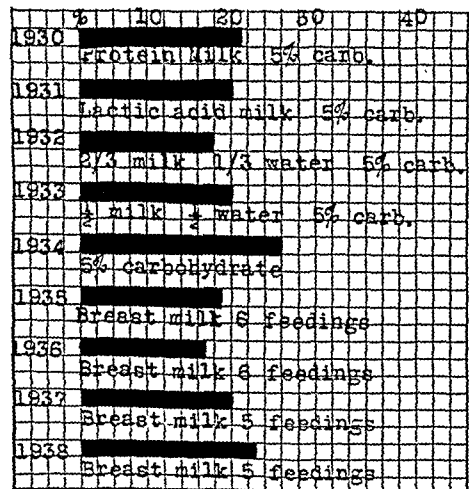

Chart 8.—Amount of breast milk; percentage of infants who received from 25 to 35 calories (1 1/4 to 1 3/4 ounces) per pound.

received breast milk when they were given complementary feedings than when they were given nothing but breast milk. This increase in the number of babies receiving small amounts of breast milk is apparently due to an actual suppression of breast milk by complementary feeding. Chart 8 shows that, irrespective of whether the baby is given a complementary feeding or receives only breast milk, about 20 per cent, or one

fifth, will receive only 1½ ounces of breast milk per pound at the end of the ten day period. This holds good for quantities as great as 1¾ ounces per pound (chart 9) as well.

With a greater secretion of breast milk, however, the story was quite different. Chart 10 shows the percentage of babies receiving 50 calories (2½ ounces) or more of breast milk per pound at the end of the tenth

Chart 9.—Amount of breast milk; percentage of infants who received from 35 to 50 calories (1¾ to 2½ ounces) per pound.

day of life. Here the result was striking. With every kind of complementary feeding except protein milk the result was the same, only 18 or 19 per cent of the babies receiving this quantity of breast milk. This clearly shows that, as was indicated in the other charts, complementary feeding suppresses the breast milk. It is shown that when protein milk was used the number of babies receiving 2½ ounces of breast milk per pound was almost three times as great as with other types of complement. This type of complement evidently does not suppress the breast milk as much as mixtures of milk and water.

In the group given no complementary feeding but nursed six times in twenty-four hours, an average of 57 per cent of the babies received 2½ ounces or more of breast milk per pound in twenty-four hours by the tenth day of life. With no complementary feedings but five nursings in twenty-four hours, an average of 41 per cent obtained this amount. It is interesting that one breast feeding a day made a difference of 16 per cent in the number of babies receiving 2½ ounces per pound in twenty-four hours.

One may summarize the effect of various feedings on the amount of breast milk obtained by the newborn infant as follows: A small number of infants will obtain nothing from their mothers irrespective of the form of feeding used. This number may be somewhat greater if a complementary feeding is given. If the mother is giving only a small quantity of breast milk, complementary feedings may further reduce her secretion of milk. With mothers who have a large or normal supply of milk, a smaller number of babies will receive sufficient breast milk (i. e. will be completely breast fed) when given any form of complementary feeding than when given breast feedings alone. Of babies who are nursed and given no complementary feedings of any kind, with six nursings in twenty-four hours more than one half (57 per cent) and with five nursings in twenty-four hours slightly less than one half (41 per cent) will

receive sufficient breast milk (i. e. will be completely breast fed) by the tenth day of life.

Before any attempt can be made to estimate the value of the various feedings studied, it is necessary to set up a standard of perfection for the neonatal period. I think that every one will agree on the first requirement, namely that the feeding should be one on which the infant can make a satisfactory gain in weight as judged by present day standards. However, the argument will then arise as to when this gain should be made: Shall the gain in weight be artificial, that is to say at the expense of physiologic loss of birth weight, or natural, on the assumption that this loss is normal?

Nature is perfectly satisfied with the phenomenon of a loss during the neonatal period of from 5 to 10 per cent of the birth weight. My studies show that the average loss irrespective of whether or not a complementary feeding is used is from 5 to 8 per cent. This loss can be lessened, as shown by these studies, with almost any form of feeding used to complement the natural supply of breast milk. According to this standard, the ideal complementary food for the neonatal period will provide as high a caloric intake as the baby can stand from a digestive standpoint. This is the answer to the first requirement of feeding during the neonatal period.

The second requirement involves the question Should the feeding suppress the normal food of the newborn infant, breast milk? I do not intend to argue this point, for it is not a part of this paper. If the physician is not interested in seeing that the infant obtains all the breast milk that its mother is able to give it, this point may be overlooked. My studies show absolutely that complementary feedings will suppress the breast milk obtained by the infant in proportion to the caloric value of the complement.

In our area the majority of mothers fortunately are anxious to nurse their babies if possible, and for this reason I have been able to avoid complementary feeding during the neonatal period. The experiences of the last two years with the omission of the night

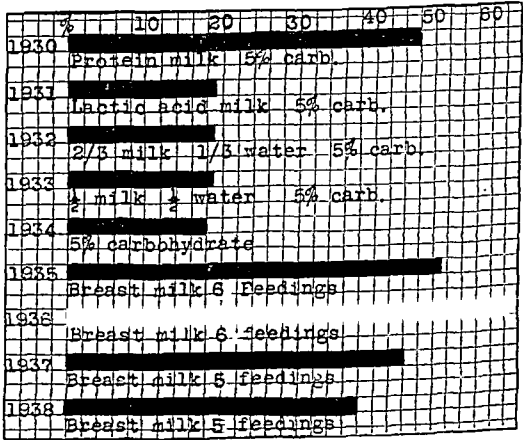

Chart 10.—Amount of breast milk; percentage of infants who received 50 calories (2½ ounces) or more per pound.

nursing leads one to believe that such omission is not a good policy. The baby does not receive quite enough food and the mother's breasts are not stimulated quite enough. I believe therefore that the nursing of newborn infants every four hours, with the avoidance of any complementary feeding except water, is, except in certain conditions, the ideal method for promoting breast feeding.

However, before this policy is adopted, one must revise the old ideas of the infant's weight curve during the neonatal period. With the method described the loss of weight during the first three or four days, before the breasts begin secreting, is considerable. It is certainly startling to see a baby drop 10 per cent or more from its birth weight during this period. Such babies, however, are in excellent condition; they are hungry and stimulate the breasts to such an extent that when the mother's milk comes they gain very rapidly. It is unfortunate that the modern tendency is to allow the mother to leave the hospital ten days after delivery and that a saying prevails that the baby should return to birth weight by the time the mother has left the hospital. With complementary feedings the loss of weight is less but the gain is slower; with no complementary feedings the loss of weight is more but the gain is greater. Such babies cannot gain sufficiently to return to birth weight by ten days, but they are well over that weight by the end of two weeks.

It must be remembered that not all mothers are able to nurse their babies completely or in part. Approximately 5 per cent will have no breast milk and approximately 9 per cent more will have hardly enough to make the effort worth while. This means that about 14 per cent of babies must be given artificial feeding altogether, and, according to the present studies, 30 per cent more may require more than breast milk. My policy is to study each baby on the seventh day of life, and, if it still weighs less than 90 per cent of its birth weight and the breast milk obtained provides less than 40 calories (2 ounces) per pound in twenty-four hours, a complementary feeding is given. This is especially true with babies of less than 6 pounds. It is ridiculous to allow such babies to become premature babies in weight while the physician is waiting for insufficient breast milk. With babies of less than 6 pounds, a complementary feeding is used earlier.

CONCLUSION

From a nine year study of 4,622 newborn infants, one may conclude that one third of all newborn infants will lose between 5 and 8 per cent of their birth weight no matter what form of feeding is given them. With complementary feedings about one half will only lose 5 per cent or less of their birth weight, and with complementary feedings of a high caloric value this figure may be increased to more than two thirds.

About one half of newborn infants (from 38 to 57 per cent) given complementary feedings will regain their birth weight by the tenth day of life. Of infants given no complementary feedings, 24 per cent of those nursed six times and 14 per cent of those nursed five times in twenty-four hours will regain their birth weight by the tenth day of life. However, this lag is due to a greater initial loss; actually the gain in weight is faster than that of infants given complementary feedings.

Complementary feedings tend to suppress the secretion of breast milk. A smaller number of newborn infants (18 to 46 per cent) will receive sufficient breast milk (50 calories or over per pound) when given some form of complementary feeding than when given breast feedings alone. Of newborn infants given no complementary feedings, 57 per cent of those nursed six times in twenty-four hours and 41 per cent of those nursed five times in twenty-four hours will receive sufficient breast milk.

952 North Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. CLIFFORD G. GRULEE, Evanston, Ill.: This question was called to my attention in the first place by the fact that an outpatient newborn service was opened. After following it pretty closely for a year or two, I found that the vast bulk of the children in the outpatient newborn service were on the breast at the termination of the lying-in period, while in the wards only about 45 per cent were leaving the hospital on the breast. I think the question of breast feeding of the newborn is largely an attitude of mind on the part of the doctor, on the part of the mother and on the part especially of the nurse. The nurse has data in the hospital from which she draws her conclusions, which data would be startling if it weren't for the newborn period. The amount of crying and loss of weight are the things that appeal to her as very serious. She forgets she is dealing essentially with a normal child, which she is. Therefore it is her tendency to give the child a bottle. It is the tendency of the doctor to submit to her entreaties, and the consequence is that the number of children on the breast is reduced. I regard this as important. Studies made about six years ago tended to show that there was markedly less mortality and morbidity among children who were breast fed, as compared with those who were artificially fed. There is one question that I think this survey Dr. Sanford has made definitely answers, and that is that women can nurse their babies. It has been repeated frequently that women today were getting to the point where they couldn't nurse their babies because of insufficiency of breast milk and inefficiency of the breast gland. This study pretty well answers that question. It isn't so much a matter of whether the breast gland is capable of functioning as it is whether it is given the proper stimulation by the baby.

DR. WILLIAM J. ORR, Buffalo: The routine procedure of giving complementary or supplemental feedings to the newborn infant to prevent physiologic weight loss or to produce a predetermined weight gain has developed into a pernicious practice. Many of us as pediatricians have been so intent on establishing arbitrary standards of food intake and weight gain that we have lost sight of the excellent facilities that nature provides for the safeguarding of the newborn. This fact has been demonstrated by Dr. Sanford and is equally evident in many private maternity hospitals where so few infants are discharged that are completely breast fed. If we are to establish successful breast feeding, it should have its origin during the infant's stay in the hospital. After his discharge, it is usually too late. The chances of successful breast feeding are lost when, more often than not, an infant leaves the hospital with half of the daily supply of food consisting of complementary or supplemental feedings. It is then only a matter of days before the child is entirely formula fed. The existing fallacious idea that a child must regain his birth weight at the time of his hospital discharge and that the initial weight loss is detrimental to his welfare is responsible for many infants being forced from the breast through the unnecessary use of accessory feedings. Unless this predetermined goal of weight gain is reached, many pediatricians feel that they have failed in their purpose and then resort to the crowding of food at the expense of breast milk. It is not to be inferred that formula feeding of the newborn is wrought with many hazards. In certain instances there are definite indications that require complementary or complete formula feeding, and when they arise this type of feeding can be successfully carried out. What should be emphasized is that human milk is still the best source of food for the newborn.

DR. HEYWORTH N. SANFORD, Chicago: With regard to Dr. Grulee's remarks about breast feeding, we are fortunate in the Chicago area in that the majority of mothers are very anxious to nurse their own babies. One who does not wish to nurse her baby is an exception. I should like to say, however, that there will always be some babies that cannot be absolutely breast fed and must be given some artificial feeding. With regard to Dr. Orr's remarks about infections and their reduction with less complementary feeding, I should like to add that with no complementary feedings to the newborn we have absolutely eliminated infections in our newborn nursery that might arise from the gastrointestinal tract.

THOUGHTS ON OFFICE PRACTICE

ALLEN GREENWOOD, M.D.

BOSTON

Having been in private practice for close to forty-nine years, I have had many interesting experiences which have led me to formulate some thoughts on what to do and what not to do in the handling of patients. An ophthalmologist who gains the confidence of his early patients will unquestionably gradually add to the number of patients who are recommended to him by those who have confidence in him.

In considering how such confidence may be inspired, I would say that there are three rules to follow: 1. Be honest. 2. Be thorough. 3. Do not criticize the work that others have done. Be willing to explain to the patient things about which he should really have a fair amount of understanding. Do not talk too much and do not promise too much. If the patient who comes before you is wearing glasses which you feel, after examination, are not suitable, simply tell him that there has been a change in the eyes and it is necessary to change the glasses. Do not bluntly state that the glasses are all wrong and that the oculist who preceded you has made a mistake. Try to follow the golden rule in your attitude toward the work of others.

I have mentioned especially the desirability of thoroughness. I cannot begin to tell the number of patients who have remarked on the thoroughness of their examination, and it is needless to say that such patients will continue to come back when they need further attention or will come back when told to. Even after so many years of practice it is easy to slip up on the necessary thoroughness.

For a moment let me indicate what I consider a thorough examination to be: (1) observation of the patient and his eyes while a careful history is being taken, (2) a good examination of the front of the eyes with oblique illumination and loupe or with the slit lamp, particular attention being paid to the appearance of the cornea, iris, pupil and lens, (3) careful use of the retinoscope, with or without cycloplegia, to determine quickly the gross refractive error, (4) careful examination of the fundus, including the peripheral portions as well as the disks and maculae, which, I feel, should never be omitted, and (5) examination with trial lenses according to some of the recognized methods of working out the refraction.

After the finding of what is considered the proper refraction, the muscle balance should be tested for far and near vision. It is my custom usually to try the fields by the confrontation method. This can be done very quickly, and if nothing is disclosed it is not necessary, ordinarily, to use the perimeter or tangent screen.

Having discovered all abnormalities about the lids, the lacrimal apparatus, the anterior portion of the eyes, the media and the fundi, and having determined what glasses, if any, are necessary, one is confronted with the task of telling the patient what it is necessary for him to do. Let me caution particularly against saying anything that will cause fear on his part. The only exception to this rule is when a melanoma or a definite glaucoma is found. In such cases it is sometimes necessary to speak with conviction and force in order to prevail on the patient to have whatever is necessary

done. Many, many times I have had a patient come into the office who had been unnecessarily frightened by a diagnosis of cataract. I have a drawing of the eye in my office showing the position and use of the crystalline lens and I use this to illustrate to the patient exactly what a cataract means so that he will not confuse a cataract with a possible tumor or cancer. Some forty-five years ago an elderly woman came to see me and I casually mentioned that her very poor vision was due to beginning cataracts. She was terribly upset and nothing I could say seemed to relieve her. She went home, went to bed and in a few weeks passed away. Her family have always felt that my telling her of the beginning cataracts was the cause of her fatal illness. It is certainly disturbing and usually requires several examinations when a patient comes in weeping copiously because some one has told her that a cataract was present in both eyes. Knowing the fear that patients have about cataracts, I seldom use the term until it becomes absolutely necessary or the patient insists on knowing the exact condition. I explain exactly what a cataract means if I have to use the term. I usually tell patients who have a few specks in the lens or a slight incipient cataract that they have a few cloudy spots in the lens of the eye and that such conditions should be watched. All patients who have incipient cataracts should be seen frequently enough to detect the occurrence of some other ocular disease which might be amenable to treatment.

Be patient with the elderly person, and if he comes back dissatisfied with the glasses do not be afraid to make a second thorough examination and then explain why the glasses do not seem as perfect as the patient thinks they should. Spend some time in telling patients how they can most easily become accustomed to the wearing of glasses for the first time or to a radical change. This is particularly necessary with patients who for the first time are getting bifocals. For the majority of patients it is wise to have a check-up on the refraction after the glasses have been worn for a while.

For patients who have conditions that require enucleation it is better to lead up to the operation gradually, even when a malignant condition is suspected.

I wish here to revert to thoroughness in the observation of the patient and in the taking of a history. Many times I have not taken as careful a history as I should. Many little hints are given by the patient when talking about his past ocular experiences. A patient may state that for some years seeing at night has been difficult so that it was hard to walk in dark places. Such a statement should lead the ophthalmologist to examine the periphery of the fundus with unusual care. The patient may also complain that he can see and read much better on a dull day than on a bright day. This calls for a more careful inspection of the nucleus of the lens with the slit lamp. The seeing of double images occasionally will call for a more careful investigation of the ocular motility. Rainbows around lights are of course suggestive of some clouding of the cornea or possibly of the lens. A careful inquiry into the family history of the patient will often lead to suggestion as to the conditions from which he is seeking relief.

In handling any patient who cannot show normal vision with either or both eyes, great efforts should be made to find out the reason. I never like to have a patient leave the office with defective vision until I have found some cause for the defect. Of course in the case of children with amblyopia in one eye it may not be possible to find any definite cause.

One can never tell what fears there may be in the mind of the patient besides those which he has expressed during the history taking. When the examination is sufficiently advanced or when it is finished and the ophthalmologist is sure that the eyes are healthy and normal, a simple statement of this fact will often do away with unnecessary fear and anxiety. Many times after I have assured a patient that there was no disease whatever in the eyes, that the vision was normal and that there was no indication of future trouble, the immense relief expressed has been very gratifying. The ophthalmologist does not need to be a psychologist to appreciate the wonderful effect of such encouragement. If, however, some chronic condition is found which is likely to progress, the ophthalmologist should be very careful not to discourage the patient. No one can tell how long a patient is going to live and no one can tell how rapidly a chronic disturbance may progress, so that all unfavorable prognoses should be refrained from so far as possible. Some thirty years ago a woman was brought weeping into my office by a friend who stated that she had just been told by one of the oldest and best oculists that she would be wholly blind in two years. Examination showed bilateral choroiditis which had not destroyed the macula, and the patient had good central vision. The patient lived for twenty-five years and just prior to her death was still able to read newspaper print. I mention this case to show how unwise it is ever to give such a discouraging prognosis. A good many instances similar to this have come under my observation. I knew of a man who was told that he had optic atrophy accompanying tabes dorsalis and would shortly be blind. He purchased a revolver immediately, and one night when he got up and turned on an electric light which had burned out and found himself in total darkness he seized the revolver and killed himself. It is better to be overoptimistic than to be unduly pessimistic. The woman mentioned, in after years, when she found that she was not going to be blind, was responsible for my seeing many prominent people.

Another practice which is helpful to all ophthalmologists is that of writing letters to the family physician of patients who may need some medical attention. I also write explanatory letters to the parents of school children who are attending school away from home. I find that these parents are cooperative and glad to get an understandable explanation of their child's condition. Sometimes these children have returned to me in later years even from long distances.

The ophthalmologist should try to give as thorough an examination to patients who for any reason are not expected to pay as to those who will pay. He must either give them his best attention or refer them to some place where they can have the proper attention. I prefer to take care of such patients myself, because one can never tell when they may refer many desirable patients to the conscientious physician.

Last, and not least, do not lose your temper with exasperating patients, especially those whom you find it impossible to make understand exactly what you are trying to do. The ophthalmologist should always remember that he is a physician as well as a specialist, and he must remember that many ocular conditions are but manifestations of some general abnormal condition, present either in the body tissues or in the general metabolism.

ONE HUNDRED PER CENT OXYGEN

INDICATIONS FOR ITS USE AND METHODS OF ITS ADMINISTRATION

WALTER M. BOOTHBY, M.D.

CHARLES W. MAYO, M.D.
Division of Surgery, the Mayo Clinic
AND

W. RANDOLPH LOVELACE II, M.D.
Fellow in Surgery, the Mayo Foundation
ROCHESTER, MINN.

The ability to administer practically 100 per cent oxygen in the inspired air, economically, efficiently and comfortably, has opened a new field for oxygen therapy. Oxygen in lower concentrations is equally efficiently administered by an apparatus that recently has been described.¹ There is a place in therapy both for low and for high concentrations of oxygen.

By administration or inhalation of oxygen in any certain percentage is meant the average amount of oxygen in the total inspired air. The amount of oxygen, after correcting for water vapor in the alveolar air, is between 5 and 6 per cent lower than whatever may be the percentage of oxygen in the inspired air.

RATIONALE OF AND INDICATIONS FOR ADMINISTRATION OF ONE HUNDRED PER CENT OXYGEN

The underlying physiologic principles and factors on which inhalation of 100 per cent oxygen is based, and the indications for its use, can be presented most conveniently in seven parts:

1. The blood transports the oxygen from the lungs to the tissues and the carbon dioxide from the tissues to the lungs. Oxygen is carried in the blood in two states: (1) a small amount in simple solution according to Henry's law of solution of gases in liquids and (2) a much larger amount in chemical combination with hemoglobin. The amount of oxygen which the blood will absorb from the air in the lungs, and will carry to the tissues, will depend in both instances on the partial pressure of oxygen in the lungs. The amount of oxygen in 100 cc. of arterial blood of the average normal individual, therefore, will be increased from about 19.5 cc. when the individual is inhaling air to 22.2 cc. when he is inhaling 100 per cent oxygen. That is, there will be an increase from 10 to 15 per cent in the oxygen content of the arterial blood.

2. At first thought, this 10 to 15 per cent increase appears to be comparatively small and possibly negligible. That this increase is not immaterial, however, depends on another factor; namely, the rate at which the blood is circulating through the tissues.

The blood as it passes through the capillaries gives up to the tissues, under normal circulatory conditions, only about 40 per cent of its load of oxygen; the venous blood, therefore, is still about 60 per cent saturated and, as is indicated in figure 1 by lines *a b c* the average partial pressure of oxygen in the capillaries will correspond to approximately 35 mm. of mercury (effect of carbon dioxide neglected).

From the Section on Metabolic Investigation (Dr. Boothby) and the Division of Surgery (Dr. Mayo), the Mayo Clinic.

Read before the Section on Surgery, General and Abdominal, at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 17, 1939.

1. Boothby, W. M.: Oxygen Administration: The Value of High Concentration of Oxygen for Therapy, *Proc. Staff Meet., Mayo Clin.* 13: 641-646 (Oct. 12) 1938. Bulbulian, A. H.: Design and Construction of the Masks for the Oxygen Inhalation Apparatus, *ibid.* 13: 654-656 (Oct. 12) 1938. Lovelace, W. R., II: Oxygen for Therapy and Aviation: An Apparatus for the Administration of Oxygen or Oxygen and Helium by Inhalation, *ibid.* 13: 646-654 (Oct. 12) 1938.

If for any reason the rate of circulation is decreased, as occurs for example in shock, the blood may give up as much as, or even more than, 80 per cent of its load of oxygen as it passes slowly through the capillaries; therefore the venous blood is only 20 per cent saturated and, as is illustrated by the dotted lines $a' b' c'$ in figure 1, will exert a pressure equivalent to approximately 14 mm. instead of 35 mm. of mercury. Now, if nothing else is done but to cause the patient to inspire 100 per cent oxygen, instead of the 21 per cent of oxygen contained in the air, the arterial blood which leaves the lungs will contain, as has been shown, 2.2 cc. more oxygen per hundred cubic centimeters. In consequence the capillary and venous blood also will contain from 10 to 15 per cent more and will be 33 per cent saturated instead of 20 per cent saturated. As is indicated by the line ABC in figure 1, there will be a corresponding increase in the partial pressure of oxygen in the capillaries, from 14 to 21 mm., which is the equivalent of a 50 per cent increase in the pressure of oxygen in the tissues.

The line ABC in figure 1 illustrates that if the patient is warmed the equivalent of 2 degrees C. the partial pressure of oxygen is increased about 3 mm., which is

Fig. 1.—Effect of changes of circulation rate and temperature on oxygen tension in capillaries.

approximately an additional 15 per cent increase; this illustrates one of the advantages obtained from increase in temperature. Another advantage obtained from the application of heat can be demonstrated when a patient is in shock. The rate of circulation of such a patient is increased, as is evidenced by a slower and stronger pulse and improved blood pressures; this increased rate of circulation tends to reverse the bad effect produced by slowing of the rate of circulation. Other measures, as for example elevation of the foot of the bed or transfusion of blood, which commonly are used in the prevention and treatment of collapse and shock, are all directed to improving the circulation of blood through the tissues so that oxygen will be delivered at a higher partial pressure. Of these various procedures, administration of 100 per cent oxygen is the most direct and specific method possible to increase the oxygen pressure in the capillaries and tissue fluids.

In traumatic surgery, either military or civil, not only is shock of frequent occurrence but often it is accompanied by direct injury to the blood vessels; this produces local slowing of the circulation in addition to the general slowing which accompanies shock. In such

conditions, administration of 100 per cent oxygen not only combats the shock but aids in preserving the injured extremity.

In civil as well as military surgery, use of oxygen unfortunately has been looked on as a therapeutic measure to be used as a last resort. It is now the custom of one of us (C. W. M.) to administer 100 per cent oxygen immediately after operation to all patients who have undergone an extensive surgical procedure. This routine procedure, in conjunction with transfusion of blood in the most severe cases, unquestionably has been beneficial to these patients. Although it is impossible to say in what percentage of cases such measures have been life saving, there is no doubt that convalescence of the patients so treated has been much more comfortable and satisfactory, from the patients' standpoint, than otherwise it would have been; this is a surgical objective which should not be neglected.

From a surgical standpoint, therefore, use of 100 per cent oxygen should not be considered to be only an additional measure for treatment of the patient after collapse or shock has developed, but rather it should be thought of and used as a measure that prevents trouble both for patient and for surgeon.

3. Whenever 100 per cent oxygen is inspired, the nitrogen in the lungs is quickly washed out. Then the nitrogen in the blood, passing through the lungs, will be diffused into the alveoli and in turn will be washed out. In a few minutes most of the nitrogen in the blood will be eliminated and then, when the blood passes through the capillaries in the tissues, it will take up additional nitrogen, carry it to the lungs and there give it off. This elimination of nitrogen from the tissues is similar to the elimination of carbon dioxide by the blood stream and lungs; the process, however, is slower with nitrogen because in the blood there are no "chemical carriers" for nitrogen as there are for carbon dioxide.

We would be remiss did we not credit Fine and his co-workers² for the splendid contribution to medicine and surgery which resulted from their demonstration that, compared with lower concentrations, inhalation of 100 per cent oxygen would rapidly remove a greater part of the nitrogen from an obstructed bowel or from the ventricles of the brain after the injection of air that is necessary in encephalography.

Those observations have been confirmed by us. However, we have found that administration of 100 per cent oxygen, in combination with use of the Wangenstein or Miller-Abbott suction method of intestinal decompression, is more efficient than either method alone. The apparatus for inhalation of oxygen here to be described is particularly convenient for these combined types of therapy, for the mask is provided with a special hole, placed in such relation to the nares that the suction tube can be passed. However, in cases of intestinal obstruction surgical measures should not be delayed too long; it is easy to be lulled into a false sense of security by the improvement in the patient's condition, including the decrease in the distention, which follows the use of 100 per cent oxygen and suction.

When, at the operating table, the debatable question arises as to whether a partially obstructed or strangulated segment of bowel should be resected, the decision can be aided by requesting the anesthetist to administer for a few minutes 100 per cent oxygen. If the color of the bowel definitely improves, the segment probably will survive, provided administration of 100 per cent

2. Fine, Jacob; Hermanson, Louis, and Frehling, Stanley: Further Clinical Experiences with Ninety-Five per Cent Oxygen for the Absorption of Air from the Body Tissues, *Ann. Surg.* 107: 1-13 (Jan.) 1938.

oxygen is started immediately after operation. On the other hand, if the color of the bowel does not improve, the segment should be removed.

The distressing gaseous distention which so frequently occurs following even some simple surgical procedure often can be relieved, or at least diminished, by administering 100 per cent oxygen. Many such patients experience great relief from gas pains, which all too frequently convert into a period of agony and otherwise normal convalescence.

4. Some types, as yet indefinitely determined, of severe headache, with or without nausea and vomiting, can be relieved by administration of 100 per cent oxygen. Fine demonstrated that the headache following injection of air for encephalography could be greatly relieved thus. In cooperation with Adson, we have completely confirmed this observation. Administration of oxygen should be started in a routine manner as soon as the encephalogram has been obtained. As a result, some patients have no headache and very little discomfort; others may have a moderate or severe headache from one to four hours and thereafter only mild discomfort. After twenty-four hours in nearly all cases there is no further distress. Likewise, we have had good results in the treatment of the headache which sometimes follows spinal anesthesia. Certain patients with that combination of headache and nausea which commonly is classified as migraine have been greatly benefited, especially those who suffered from the type of migraine which is associated with prodromal symptoms; if 100 per cent oxygen can be given during the prodromal period, the attack of migraine may be aborted. The alcoholic headache and nausea which occur "the morning after" sometimes can be relieved, especially if administration of oxygen is combined with physical exercise or heat. In a few cases the nausea and vomiting of seasickness have been relieved.

In all these conditions the beneficial effect can be directly attributed to the relief of the anoxemia which results from circulatory collapse. For example, in cases of severe seasickness the greenish yellow ashen pallor of the patient, the nausea and vomiting, cold beads of perspiration on the forehead, the weak and thready pulse are all symptoms indicative of peripheral circulatory collapse or shock, a syndrome, as we wish to emphasize, which always is benefited even if not entirely controlled by the administration of 100 per cent oxygen.

5. The organisms of gas gangrene and of tetanus are known to be anaerobic. Therefore, in these diseases the prevention of anoxia in the tissue by the inhalation of 100 per cent oxygen which, as we repeat, will increase the oxygen pressure in the tissues between 50 and 100 per cent, is a direct and specific method of combating these diseases. In addition, in cases of gas gangrene the subcutaneous emphysema which results from the presence of hydrogen and nitrogen is rapidly removed; thereby pressure on the capillaries is decreased, thus permitting increase in the rate of circulation of blood, which still further elevates the oxygen pressure in the tissues.

It is possible that the pathogenicity of some other organisms may be reduced when they are exposed to high concentrations of oxygen; as yet this field has been explored little but preliminary results justify further investigation. Even if the infection itself is not influenced, the circulatory collapse which accompanies septicemia, peritonitis and similar conditions can be relieved, at least in part, by administration of 100 per cent oxygen.

6. The symptoms which accompany acute, massive atelectasis are greatly benefited by administration of 100 per cent oxygen. This condition is characterized by the sudden onset of severe dyspnea and cyanosis. These manifestations are due to the continued circulation of blood through that part of the lungs from which all, or nearly all, exchange of air is prevented by the presence of a plug of mucus or of some other obstruction to a bronchial tube. The blood which courses through this region receives no oxygen; therefore the mixed blood of the pulmonary artery is incompletely saturated. Inhalation of 100 per cent oxygen will increase the amount of oxygen in the blood which passes through the aerated portions and thus will partially compensate for the deficiency. In addition, if plugging of the bronchus is not complete the amount of oxygen which will diffuse down into the partially collapsed portions will be increased and the oxygen pressure in the alveoli will be augmented; thus, the average saturation of the arterial blood with oxygen will be still further increased. Frequently the relief thus obtained is rapid and spectacular; in some instances, however, as has been recommended by Moersch, procedures such as bronchoscopy and removal of the mucous plug must be adopted.

In acute pulmonary edema the inhalation of 100 per cent oxygen is of very great benefit; in some cases, as suggested by Barach, its inhalation under slight positive pressure (5 cm. of water) has an additional favorable effect. Pulmonary embolism is another condition in which the dyspnea, distress, anoxemia and resulting shock in some instances can be dramatically relieved.

7. Many types of heart disease will respond more favorably to a standard therapeutic procedure if 100 per cent oxygen also is administered. Relief of the pain of angina pectoris sometimes is obtained with striking rapidity.

LACK OF PULMONARY IRRITATION FROM INHALATION OF 100 PER CENT OXYGEN

In the past eight months, by means of our apparatus for inhalation of oxygen, we have administered 100 per cent oxygen to more than 800 patients without observing the slightest evidence of pulmonary irritation. Except in a very few cases, however, we have not administered 100 per cent oxygen continuously for more than forty-eight hours. We recommend, for the present at least, that this length of time be not exceeded and that thereafter the flow of oxygen and the airports be so adjusted that the patient receives from 50 to 70 per cent oxygen. On the other hand, we have administered 100 per cent oxygen intermittently for several days without the slightest trace of pulmonary irritation.

APPARATUS FOR INHALATION OF OXYGEN

The apparatus for inhalation of oxygen which we have used was devised by two of us together with Bulbulian¹ and is known as the B. L. B. inhalation apparatus. It consists of three parts: the mask, the connecting-regulating device and the reservoir-rebreathing bag.

The Mask.—For use in aviation as well as for the treatment of patients over long periods of time it was essential that the mask be so designed not only that it would be comfortable but also that it would fit perfectly. Two types of interchangeable masks were designed: one, the nasal type (fig. 2), leaves the mouth free for talking, eating or drinking, which is a decided advantage for prolonged use; the other, the oronasal type (fig. 3), covers both nose and mouth and is for use by individuals who have nasal obstruction or who are mouth breathers. Because the basic design conforms

to the underlying bony structures, which are much less variable than the overlying soft tissues, it was found that only two sizes of each type of mask were needed in order to obtain satisfactory and comfortable fit for an individual of nearly any size who had passed the age of 10 years.

The Connecting-Regulating Device.—A metal connecting and regulating device connects the mask to the reservoir-rebreathing bag. The oxygen inlet tube passes

Fig. 2.—Nasal type of mask in use.

through this metal device, turns downward and conducts the oxygen into the lower part of the bag. It is provided with a rotating sleeve which is pierced by three small openings or airports which can be brought into registry with similar openings in the main tube by turning the sleeve. When it is desired to administer 100 per cent oxygen, these airports are closed; when it is desired to dilute the oxygen with air, one, two or three of the airports are left open. In addition, there is an expiratory valve provided with a spring under slight tension, which permits escape of expired air over and above that amount which is just sufficient to tend the reservoir-rebreathing bag without causing any appreciable resistance to expiration. By adjusting the airports and regulating the flow of oxygen from the oxygen tank, any desired proportion of oxygen and air can be administered.

The Reservoir-Rebreathing Bag.—The reservoir-rebreathing bag is of such size that it will contain slightly less than the volume of air contained in one expiration under the conditions in which the apparatus is being used. For practical purposes a bag of a capacity of 500 cc. can be used in nearly all instances. The primary object of the bag is to conserve, for inhalation on the following inspiration, the oxygen which is flowing continuously from the tank during expiration. Expiration usually occupies about two thirds of the respiratory cycle. The bag also increases the efficiency of the apparatus in the utilization of oxygen because it collects, in addition to the oxygen flowing in from the oxygen tank, the first part of the expired air, which comes in large part from the "dead space" of the upper part of the respiratory tract and contains the largest amount of oxygen and the least amount of carbon dioxide of any part of the expired air. There is always less than 1 per cent of carbon dioxide in the bag from the air. Enough moisture is present in the bag from the previous expiration to provide a comfortable humidity.

Accessory Apparatus.—In addition to the apparatus for inhalation of oxygen, a reducing valve and flowmeter are necessary parts of the equipment. Any type of reducing valve and flowmeter manufactured by a reliable concern can be used. The

flowmeter should be graduated in liters of flow per minute. A float or kinetic type of flowmeter is preferable to one of a pressure type because the latter is more likely than the former to get out of order and give inaccurate readings, especially for the small rates of flow used in conjunction with our inhalation apparatus. Flowmeters should be doubly calibrated so that they can be used to indicate the rate of flow of pure oxygen or of the mixtures of 80 per cent helium and 20 per cent oxygen that are used for the treatment of asthma; by having the double calibration, all reducing valves and flowmeters can be used interchangeably for straight oxygen therapy or for helium-oxygen therapy. Unfortunately, at present, the large cylinders are equipped with two types of valves which have different threads. Therefore a small "adapter" always should be on hand so that the reducing valve can be attached to either type of cylinder valve.

USE OF APPARATUS

If the patient is not a mouth breather, usually he prefers the nasal type of mask rather than the oronasal type of mask.

Each type of mask is made in two sizes: Mask 1 is the nasal mask for men, or for women with large faces; mask 2 is the nasal mask for women or for men with small faces; mask 4 is the oronasal mask for men and mask 5 is the oronasal mask for women. First the appropriate size and type of mask for an individual is selected by placing different masks on the patient's face. Then the rubber tube that runs from the reducing valve and flowmeter (these are attached to the connecting-regulating device. The oxygen is turned on so that the flow is about 6 or 8 liters per minute, depending on depth and rate of respiration. Next the mask is adjusted in place. In most instances the mask is most comfortably held in place by passing the rubber retaining strap around the back of the head or neck just below the ears; in some instances other positions are better. The length of the strap should be carefully adjusted before it is fastened, so that tension is sufficient only to hold the mask gently against the face. The metal pieces on the

Fig. 3.—Oronasal type of mask in place.

mask, which hold the strap in place, can be bent slightly to aid in making the mask fit accurately; it need not be strapped on so tightly that it is uncomfortable even when worn constantly for days. A glance at the reservoir-rebreathing bag will tell whether the apparatus is properly adjusted to prevent a significant leak, because the bag expands nearly to capacity on expiration and contracts on inspiration.

Adjustment for Inhalation of 100 per Cent Oxygen.—When it is desired to administer approximately 100 per cent oxygen in the inspired air, all three of the port-

holes in the connecting-regulating device should be closed by properly rotating the airport sleeve; the valve which controls the flow of oxygen on the reducing valve should be so adjusted that the flowmeter indicates that from 6 to 8 liters (more if the patient is breathing deeply) is being delivered. After the patient has become accustomed to the apparatus, the rate of flow often can be reduced to 5 or 7 liters per minute. However, at all times when it is desired to give 100 per cent oxygen in the inspired air the rate of flow should be sufficient that the reservoir-rebreathing bag does not completely collapse on inspiration. When all the airports are closed, if the rate of flow of oxygen is not sufficient to prevent the bag from completely collapsing there will develop a sudden, marked resistance to completing the inspiratory cycle, which may frighten the patient if it occurs before he is completely accustomed to the apparatus.

Adjustment for Inhalation of from 50 to 60 per Cent Oxygen.—When it is desired to administer from 50 to 60 per cent oxygen in the inspired air, that is, to use the concentration of oxygen that commonly is employed in the best run oxygen tents, then the rate of flow of oxygen from the tank, as measured by the flowmeter, should be 4 liters per minute for a large adult and slightly less for a small individual; the rotating sleeve on the connecting-regulating device of the inhalation apparatus should be so turned that two holes are open. These holes permit, automatically, the addition of the proper amount of air, when the flow of oxygen is 4 liters per minute, to cause the inspired air to contain between 50 and 60 per cent oxygen. When oxygen diluted with air is being administered and the two airports are open, the reservoir-rebreathing bag completely collapses on inspiration and the patient automatically obtains the remaining amount of his inspired air through the open airports. Note that complete collapse of the reservoir-rebreathing bag is permissible when the airports are opened and it is desired to administer oxygen diluted with air, but that it is not permissible when it is desired to administer 100 per cent oxygen.

NURSING ATTENTION

In adjusting the mask to the face, the nurse should be careful not to have the retaining strap too tight. Tension of the strap should be sufficient only to hold the mask in place and it is sufficiently tight if the reservoir-rebreathing bag is moving up and down regularly with each respiration. Whenever the nurse passes the patient she should glance at the reservoir-rebreathing bag; if it is not moving, only a moment is necessary to adjust the mask properly. To keep the patient comfortable the mask should be removed at intervals of about two hours and the patient's face washed, the skin dried and talcum powder applied. If the patient is at home, any competent member of the family can be taught in a few minutes just what to do. In fact, when the mask is used in the prodromal stage of certain types of migraine to abort an attack, the patient can be taught in a brief time the entire technic of administering the oxygen to himself at home.

COST OF OXYGEN THERAPY

Up to now the high cost of oxygen therapy has acted as a deterrent to its general use early in the course of an illness. To administer oxygen by a tent costs the patient from \$12 to \$25 a day, without allowance for the special nursing which is usually a necessity. By use of the B. L. B. inhalation apparatus the cost of oxygen therapy should average only \$5 to \$8 a day, while at the same time the oxygen will be given more efficiently and can be given in higher concentration and in most cases without reduction in comfort. For administration of 100 per cent oxygen the average rate of flow will be 6 liters per minute. This will require the use, daily, of approximately one and one-half large cylinders of commercial size; to administer 60

per cent oxygen on the average requires 4 liters per minute and this means that one large cylinder of commercial size will be sufficient for twenty-four hours. On account of the high cost, tanks smaller than the standard commercial size should be used only for convenience of transportation in emergency.

Naturally, the cost of a large cylinder of oxygen varies in different localities, depending on the amount of oxygen used in that locality and the distance from an oxygen manufacturing plant. The freight is a large item, for the cylinders are heavy and must be transported in both directions. There is no difference between commercial oxygen and medical oxygen; therefore in smaller localities the price of oxygen often is determined by the price that garages or small oxyacetylene welding plants pay for their supply of oxygen. As a rule the smaller oxyacetylene welding shops pay between \$3.50 and \$4 (f. o. b. producing plant) for a large commercial tank containing 220 cubic feet, or 6,230 liters, of oxygen. The total cost of a tank of oxygen, including freight, therefore should be from \$3.75 to \$5. Medical users should not have to pay more unless they demand emergency service and delivery at night. The cost of extra delivery service should be distinguished from the regular cost of the oxygen, as such service will be needed only in emergencies, when the patient is seen for the first time at night. Hospitals which use large quantities of oxygen of course would get better rates than users of small quantities.

SUMMARY AND CONCLUSIONS

The oxygen inhalation apparatus devised by two of us, together with Bulbulian, will greatly decrease the cost of oxygen therapy. Its use will increase the availability to the general public of oxygen therapy and of helium-oxygen therapy, because the apparatus is as suitable for use by the family physician, in the patient's home, as it is in large, well equipped hospitals. Furthermore, the scope of oxygen therapy is broadened because the oxygen can be given in any concentration up to pure oxygen, thus enlarging the field of treatment to include diseases that are benefited by high concentrations of oxygen and which do not respond much, if any, to lower concentrations. Inhalation of 100 per cent oxygen does not cause pulmonary irritation if administration is not maintained continuously for more than two days; after two days, lower concentrations should be used.

The conditions which chiefly can be benefited by, and often prevented by, early inhalation of 100 per cent oxygen are traumatic or surgical collapse or shock, abdominal distention, headache following encephalography, certain types of migraine, profuse pulmonary edema, massive collapse of the lung, pulmonary embolism, angina pectoris and some other cardiac conditions, infections due to anaerobic organisms such as those of gas gangrene and tetanus, and possibly certain infections due to partially anaerobic organisms.

Oxygen therapy should be used early in the course of a disease, as an adjunct to other well established procedures. It is not a panacea. It is rarely of value as a last resort.

ABSTRACT OF DISCUSSION

DR. ALVAN L. BARACH, New York: As the authors pointed out, the special advantage of inhaling 100 per cent oxygen over 50 to 60 per cent oxygen is a substantial increase in the amount of oxygen in physical solution in the blood plasma. That means that the oxygen is under a much increased pressure to leave the blood and go into the tissue cells. What are the indications for administration of 100 per cent oxygen, in addition to those mentioned? What are the contraindications, what are the dangers, what is the best method to use? The so-called medical shock or peripheral circulatory failure is the primary indication. This may occur in pneumonia, in heart failure, in coronary occlusion, in which the additional tension of oxygen in

capillary blood may make all the difference between an inadequate and an adequate functioning heart muscle. The extra amount of oxygen in physical solution in the blood is of considerable importance in that type of case. Patients with severe asthma frequently develop pulmonary distention, acute functional emphysema, and that distended condition of the lung interferes with their response to routine treatment. These patients, inhaling intermittently a mixture of oxygen with helium for from three to five days, will get rid of their pulmonary distention and their severe asthma at the same time. I have found it valuable to give 100 per cent oxygen at the conclusion of forty-five minutes' treatment of 20 per cent oxygen mixed with 80 per cent helium. The B. L. B. apparatus is to my mind superior to any mask yet devised in comfort and effectiveness. It is useful in administering 100 per cent oxygen and as a simple method of giving helium with oxygen. If a patient cannot take the mask comfortably, the oxygen tent, the oxygen face tent or the helium-oxygen hood should be employed. A few words about the contraindications of 100 per cent oxygen: In animals, regularly after two to four days of continuous inhalation of 100 per cent oxygen, irritative changes appear in the lungs. These experimental pathologic observations have to be borne in mind. I still think it is safe to limit the use of 100 per cent oxygen to not longer than two days; or, as an alternative procedure, as in certain cases of chronic congestive heart failure, to give 100 per cent oxygen twelve hours of the day and 50 or 60 per cent oxygen the rest of the time.

DR. JACOB FINE, Boston: Until the mechanism of the symptoms following encephalography is better understood, it will be difficult to say whether the relief afforded by breathing 100 per cent oxygen is caused by correcting cerebral anoxemia or by the absorption of the air. One hundred per cent oxygen inhaled for one, two or three hours promptly and dramatically cures the headache and relieves the nausea, and the air is effectively removed from the subarachnoid space and the ventricles. In intestinal distention the primary role of the 100 per cent oxygen lies in its ability to facilitate the more rapid elimination of nitrogen from the intestine rather than in any direct effect of oxygen on tissue function. A decrease in intra-intestinal pressure and the resulting restoration of effective peristaltic activity and improved absorptive function are the achievements which 100 per cent oxygen affords in the nonobstructing types of distention. It would, however, be a grave mistake to place chief reliance on this agent in a case of mechanical obstruction. When the patient's condition will not permit immediate surgical procedures, the use of 100 per cent oxygen, like that of the Miller-Abbott tube, may by its decompressive action be relied on to restore the patient to a better physiologic state and therefore convert the patient from a bad risk to a good risk. As to the relative merits of 100 per cent oxygen and the Miller-Abbott tube, it is clear that the tube, once it passes the pylorus, leaves little to be desired, except in closed loop obstruction, which it obviously cannot relieve, and in which case oxygen has the advantage. There are patients who cannot swallow or will not retain the tube. And there is the occasional instance in which the tube will not pass through the pylorus. In these instances oxygen will serve satisfactorily or may be given while one is awaiting successful passage of the pylorus, which may be a matter of many hours. My experience with the B. L. B. mask has been altogether satisfactory and confirms in every respect what the authors have said about it. We have found it far less cumbersome than any oxygen tent, more economical, and more comfortable for the patient.

DR. WALTER M. BOOTHBY, Rochester, Minn.: I want to agree with Dr. Barach that 100 per cent oxygen should not be used consistently and consecutively for more than thirty-six to forty hours. After this length of time, if further oxygen therapy is indicated, the concentration of oxygen in the inspired air should be reduced to approximately 60 per cent. When using our B. L. B. inhalation apparatus this is done by reducing the rate of flow of oxygen from 6 or 8 liters per minute, with all holes closed in the connecting-regulating device, to about 4 liters per minute and at the same time opening up two or three of the holes in the connecting-regulating device to admit the admixture of air.

TORULOSIS INVOLVING THE HUMAN CEREBRUM

WILLIAM EGBERT ROBERTSON, M.D.

HAROLD F. ROBERTSON, M.D.

HELENA RIGGS, M.D.

AND

LEON SCHWARTZ, M.D.

PHILADELPHIA

Torulae are yeast-like fungi which occur widely disseminated in nature. They are found on trees, flowers, fruits and insects and are of the genus *Cryptococcus*. The medical significance of this yeast is its pathogenic production of a cystic blastomycosis in man and certain animals. An accurate estimate of the incidence of torulosis is impossible to determine. This is because the condition is not sufficiently well recognized by the profession at large. The report under discussion constitutes the most recent of sixty-four cases appearing in the medical literature. There are probably numerous instances which go unreported because of failure of diagnosis. The protean manifestations of *Torula histolytica* leads us to believe this disease worthy of special mention.

BIBLIOGRAPHY

Robert Hooke¹ in 1656 was the first to describe fungous disease. In 1901 Bertarelli and Calamida² described yeasts as etiologic factors in throat and tonsil infections. Frothingham³ in 1902 reported the occurrence of an equine lung involvement. Stoddard and Cutler⁴ were the first, in 1916, to give a satisfactory description of the clinical and pathologic characteristics. Freeman and Weidman⁵ in 1923 gave a critical analysis of the classification and cultural characteristics of *Torula*; in 1931 Freeman⁶ reported a comprehensive survey of forty-three cases. Mitchell⁷ in 1936 pointed out a close resemblance in some instances to Hodgkin's disease. Levin⁸ in 1937 formulated an analytic table comprising a total of sixty cases.

CLINICAL MANIFESTATIONS OF TORULA

The onset of the disease is insidious and the course is chronic, thus producing an undetermined clinical picture. Numerous systems may be involved, among which are the lymphatic and central nervous systems. Rarely a visceral involvement occurs, the lesion being found in the kidneys, liver, spleen, bone marrow, lungs, thyroid, adrenal capsule and rarely the skin. The physical symptoms and signs, therefore, largely depend on the type of involvement present. Infection of the lymphatic system produces lymphatic tumors which resemble Hodgkin's disease. Central nervous system invasion suggests tuberculous meningitis, intracranial neoplasm or abscess. The latter two conditions are

so realistically simulated that subtemporal and suboccipital decompressions have been erroneously performed in an effort to establish a diagnosis. An analysis of the reported cases includes the following: encephalitis, psychosis, dementia paralytica, pneumonia or intrathoracic neoplasm, granulomatous acneiform cutaneous eruption (rare), pelvic and inguinal abscess, ulcerations of the tongue, tumor masses in the nasopharynx with destruction of the soft palate, suppurative otitis media and sarcoma of the tibia.

Infection of the central nervous system is by far the most frequent occurrence. The insidious onset may be accompanied by headache, nuchal rigidity, vomiting, visual disturbances, paresis or paralysis, convulsions and coma. In many instances only inanition, personality changes and a progressive failure ensue, usually unaccompanied by other signs of bacterial or parasitic invasion such as leukocytosis and fever. Other cases have shown a low grade temperature elevation with leukocyte counts varying from a leukopenia to 25,000 or more.

The portal of entrance is undetermined and may include the pharynx, accessory nasal sinuses, tonsils, middle ear and gastrointestinal tract. The widespread occurrence of the torulae on vegetation and insects would suggest the respiratory or digestive tracts as the avenues of admission.

The duration of the disease may be weeks, months or years and the fatality is 100 per cent. Antemortem diagnosis is made by the demonstration of the yeast-like budding, gram-positive fungi in the spinal fluid. Cultures of the fungi have been obtained from the spinal fluid, lymph nodes, respiratory tract, blood and urine.

plained of generalized weakness which had become progressively worse during the past six weeks. He considered himself in good health until four years before, at which time an attack of herpes zoster on the right chest and abdomen resulted in intermittent asthenia. His practice was greatly curtailed because of insufficient strength to carry on continuously during the past four years. Six weeks before admission, while shaving, he was suddenly seized with severe weakness and fell to the floor, fully

Sabouraud's medium is the most desirable for maximum growth. Rats, mice and guinea pigs are the experimental animals of choice. Spontaneous occurrence of torulosis has been reported in the horse as well as in the chetah.

REPORT OF CASE

History.—W. S. R., a physician aged 61, referred by Dr. Sherman F. Gilpin Oct. 29, 1937, to the medical service of Dr. W. E. Robertson at the Philadelphia General Hospital, com-

conscious. During the four years of ill health, dizzy spells, syncope, dimness of vision and photophobia were frequent. At times there was incontinence of feces and urine. The mental status showed a steady decline with memory failure and ultimately complete disorientation. His health prior to four years before was good, except for typhoid at 20 years of age, and the family history revealed nothing of importance.

Physical Examination.—The patient's nutrition was remarkably good. He was cooperative but mentally hazy. The eyes showed vertical nystagmoid movements. The cardiovascular and respiratory systems were essentially normal except for advanced arteriosclerosis of the fundi and peripheral arteries. The blood pressure was 110 systolic, 70 diastolic. A coarse tremor existed in the hands and tongue, and the extremities showed muscle atrophy with severe loss of motor function. The neurologic examination by Dr. B. P. Weiss revealed that the eyeballs were somewhat prominent. There was tremor of the hands. The pupillary reaction, eye muscles and other cranial nerve functions were intact. There was generalized muscle weakness, as noted by resistance to passive motion. No ataxia was present in the upper extremities but there was some incoordination in the lower limbs, which could be explained by muscular weakness. All deep tendon reflexes were hyperactive with the exception of the patellar and achilles, which were hypo-active. A suggestive Babinski sign was present on the left. No clonus was elicited. The peripheral arteries were sclerotic. The patient was mentally disoriented and confused, with impairment of memory for recent and remote events. There was apparently diffuse cerebrospinal arteriosclerosis. The medical department made a provisional diagnosis of myasthenia gravis.

Laboratory Studies.—Repeated urinalyses revealed an occasional trace of albumin and specific gravity of 1.022 to 1.033. The red blood cells were 4,230,000 with 95 per cent hemoglobin and white blood cells 17,000. Polymorphonuclears were 92 per cent, lymphocytes 7 per cent and mononuclears 1 per cent. The Kahn test and the Wassermann were negative. Repeated blood cultures showed no growth. Blood bromides were absent, calcium 9.6, phosphorus 5.2 and serum

sodium chloride 550. Blood sugar and urea nitrogen were within normal limits except terminally, when the latter rose to 35. Gastrointestinal examination including feces and gastric analysis were essentially normal. The typhoid, paratyphoid A and B and *Bacillus abortus* agglutinations, as well as the icterus index, added no confirmatory diagnostic aid. The cholesterol varied from 30 to 164 with corresponding esters of from 46 to 66 per cent respectively. A bromsulphalein test showed 7 per cent retention after thirty minutes. Total proteins ranged from 5.8 to 6.8 with no inversion of the albumin-globulin ratio. The spinal fluid was not under increased pressure and contained 123 cells, of which 50 per cent were polymorphonuclears, 44 per cent lymphocytes and 6 per cent endothelial cells. No tubercle bacilli or other bacteria were demonstrable, the chlorides were 650, sugar was 22 and the Wassermann reaction was negative. Our failure to suspect *Torula* infection prevented a thorough search for yeasts or inoculation of centrifuged spinal fluid on Sabouraud's medium. A pulmonary roentgenogram, as well as an electrocardiogram, was essentially normal. Cystoscopic examination demonstrated a neurogenic bladder with marked pallor of the mucosa. A low grade fever was continuously present with moderate elevation of temperature and respiration. Histologic examination by Dr. R. P. Custer of a muscle biopsy ruled out myasthenia gravis.

Clinical Progress.—The patient remained confused, disoriented and delusive. His speech was slow, hesitant and frequently incoherent, with the basic trend of thought dwelling on his experiences in the practice of medicine. He was totally incontinent of feces and urine. The asthenia progressed to a state of mental and complete physical dissolution, coma and death on Jan. 20, 1938. Treatment consisted purely of attempts at symptomatic relief. Had the true causative agent been suspected, compound solution of iodine 25 minims (1.5 cc.) in 100 cc. of physiologic solution of sodium chloride would have been administered intravenously on alternate days with the hope of some therapeutic action on the cystic blastomycosis.

Necropsy Report.—The gross examination as reported by Dr. G. H. Craddock showed marked emaciation and atrophy of the skeletal muscle system. There were a confluent bronchopneumonia of the right upper lobe, bilateral healed apical tuberculosis and atelectasis of the left lower lobe and healed tuberculous mediastinal nodes. Benign nephrosclerosis and myocarditis completed the picture. The gross appearance was corroborated by the microscopic examination.

Examination of the nervous system was made by Dr. Helena Riggs. The pituitary fossa was eroded and funnel shaped. The pia-arachnoid was thick and dense, like the boiled white of an egg. There was enormous dilatation of the subarachnoid space. The cerebellar tonsils were crowded together so that the cisterna magna was obliterated and the vermis compressed. The lateral and third ventricles were enormously dilated, constituting "hydrocephalus ex vacuo." The circle of Willis was extremely hypoplastic and anomalous in formation.

Microscopic examination revealed infiltration of the subarachnoid space with lymphocytes and plasma cells in association with large multinucleated foreign body giant cells. Contained in the giant cells and also free were numerous cells larger than the plasmocytes. These showed a clear refractile capsule and a central round body bristling with spikes, basophilic in type. These appeared to be spores with occasional budding. The exudate and spores were also massed around and within the choroid plexus at the level of the aqueduct. There was a chronic inflammatory reaction in the ependyma of the whole ventricular system with formation of subependymal nodules. The exudate was present over the vertex and base as well as in the subarachnoid space of the cord. The optic nerves showed dense extension of the exudate along the perivascular spaces with a beginning invasion of the tissue itself. There was also severe parenchymatous degeneration of the entire nervous system. Considering the very small and anomalous cerebral vascular tree, it would appear that cerebral circulatory insufficiency as well as the torular infection was an etiologic factor in the parenchymatous changes. There was evidence of more recent focal areas of degeneration, including an area of chronic incomplete softening in the anterior segment of the pallidum which might have been attributed to the effect of the infection on the cerebral circulation.

In the light of the clinical evidence of severe muscular atrophy and muscular weakness, it is of interest that the pyramids in the medulla and the entire spinal cord showed signs of parenchymatous degeneration with glial reaction. This may have been due to interference with circulation in the anterior and posterior spinal arteries at their point of origin, since it was noted that these vessels had been compressed as a result of the chronic cerebellar herniation. The diagnosis of torular meningitis was confirmed by Dr. Fred Weidmann.

SUMMARY AND CONCLUSIONS

Torulosis, a yeastlike cystic blastomycosis, is an occasional pathogen of man. The clinical importance of this infection lies in the multiplicity of its systemic involvement, the most frequent of which is the central nervous system. An entity which may closely simulate Hodgkin's disease, tuberculous meningitis, intracranial and thoracic neoplasm, as well as other maladies, offers a perplexing diagnostic problem worthy of more than passing interest to the practitioner of medicine and surgery.

327 South Seventeenth Street.

HISTOPLASMOSIS OF DARLING

FOURTH CASE TO BE REPORTED IN UNITED STATES

FRANK J. SHAFFER, M.D.

JOHN F. SHAUL, M.D.

AND

REGINALD H. MITCHELL, M.D.

WASHINGTON, D. C.

Histoplasmosis of Darling (Darling's disease) is a rare disease entity. As far as can be ascertained, until 1934 only seven cases¹ had been reported in the medical literature, all of which had occurred in the Western hemisphere. Four were found in the tropics: three in Panama and one, in which the diagnosis was histoplasmosis of the lung,² in Honduras. The remaining three were reported from Minnesota, California and Tennessee, respectively. The racial distribution was varied. Of the four patients in the tropics, two were Martinique Negroes, one a Chinese and the fourth a "native" of Honduras. The patients in the United States were a mulatto and two members of the white race, one of them an infant, none of whom had ever been in the tropics or had had any contact with tropical areas. Only in the case reported by Dodd and Tompkins was the diagnosis made during life by the discovery of the parasite in supravital stained blood smears. The organism was also successfully cultured from the tissues post mortem.

From the Medical and Laboratory Services of the Children's Hospital, Capt. Elbert DeCoursey, United States Army Medical Corps, gave assistance and advice.

1. These are the cases reported: Darling, S. T.: A Protozoan (a) General Infection Producing Pseudo-tubercles in the Lungs and Focal Necrosis in the Liver, Spleen, and Tubercles in the Lungs and Focal Necrosis in the Liver, Spleen, and Tubercles in the Lungs, *J. A. M. A.* **46**: 1283 (April 28) 1906; (b) Histoplasmosis: A Fatal Infectious Disease Resembling Kala-Azar Found Among Natives of Tropical America, *Arch. Int. Med.* **2**: 107 (Sept. 15) 1908; (c) The Morphology of the Parasite (Histoplasma Capsulatum) and the Lesions of Histoplasmosis, a Fatal Disease of Tropical America, *J. Exper. Med.* **11**: 515, 1909, and Maryland *M. J.* **1**: 125, 1907.

- Phelps, B. M., and Mallory, F. B.: Toxic Cirrhosis and Primary Liver Cell Carcinoma Complicated by Histoplasmosis of the Lung, Fifteenth Annual Report, Medical Department, United Fruit Company, 1926, p. 115.
- Dodd, Katherine, and Tompkins, Edna: A Case of Histoplasmosis of Darling in an Infant, *Am. J. Trop. Med.* **14**: 127-137 (March) 1934.
2. Because of atypical postmortem appearances the diagnosis of histoplasmosis is questioned in this case by some writers: DeMonbrun, W. A.: The Cultivation and Cultural Characteristics of Darling's Histoplasma Capsulatum, *Am. J. Trop. Med.* **14**: 93 (March) 1934. Ciferri, R., and Redaelli, P.: *J. Trop. Med.* **37**: 278 (Sept. 15) 1934.

We feel that our case merits attention, since it is the eighth case of histoplasmosis to be reported in the medical literature and the fourth in the United States. In spite of its apparent rarity, we believe that the disease may be more common in this country than is generally believed, and for this reason its clinical picture, pathology and possible epidemiologic aspects deserve the interest of the medical profession.

REPORT OF CASE

History and Examination.—F. C., a white girl aged 11 months, was admitted July 22, 1938, to Children's Hospital in the services of Drs. Kirby Smith and Reginald H. Mitchell, having been referred for hospitalization from Paconian Springs, Va., by Dr. W. C. Barr. The patient's illness dated from the early part of January 1938, when at the age of 6 months she had been weaned and given a formula containing cow's milk obtained from a cow owned by her parents. About three weeks later she began to suffer from intermittent fever and projectile vomiting two or three times daily after feedings. One month prior to admission she exhibited marked drowsiness accompanied by intermittent fever and periods of alternating diarrhea and constipation.

The past history was essentially negative. The patient was born prematurely at the age of 7 months, the birth weight being 3 pounds 14 ounces (1,780 Gm.). Labor was induced because of the mother's hypertension. The infant, apparently normal at birth, had developed satisfactorily until the onset of the last illness.

The family history was irrelevant. The parents were of English, Irish and German extraction and lived on a farm several miles from Paconian Springs, Va. The mother's health had always been poor and she had suffered from "kidney trouble" since an attack of scarlet fever in late childhood. She had never had other children. Neither the parents, the patient nor the immediate associates had ever been out of the state of Virginia.

the skin of the hands and feet. Over the left lower costal area there was a slightly elevated soft white lesion measuring approximately 4 cm. in diameter. The heart rate was rapid, and a systolic murmur could be heard over the pulmonary areas. The spleen extended down to the iliac crest, and the liver was palpable 6 cm. below the right costal margin in the midclavicular line. The other results of physical examination were of no significance.

Fig. 2.—Section of adrenal under high power ($\times 1,600$) showing parasitic bodies in endothelial cells in the medullary portion.

Because of the clinical picture (hepatomegaly, splenomegaly and the condition of the blood), a diagnosis of aleukemic leukemia was made.

Course.—From the day of admission the patient's course was rapidly downward. Gavage feedings and nearly daily hypodermoclysis, intravenous infusions of dextrose and transfusions

Fig. 1.—Section of adrenal under low power ($\times 880$) showing many reticulo-endothelial cells loaded with parasitic bodies. E, endothelial cells.

In summary, this infant was admitted with a history of intermittent fever and vomiting of six months' duration, drowsiness, and alternating diarrhea and constipation of one month's duration.

At physical examination on admission the child appeared malnourished and slightly dehydrated. She weighed $8\frac{1}{2}$ pounds (4 Kg.) and had a rectal temperature of 103.2 F. There was slight ptosis of the left eye, and the teeth were absent. Bilateral cervical adenopathy was noted, as well as scaling of

were required to maintain nutrition. For the first ten days following admission the temperature fluctuated between 98.6 and 103 F. From the tenth day on there was sustained pyrexia, the temperature ranging from 101 to 105 F. No increase in the size of the liver and spleen was noted during the hospital stay. August 2, twelve days after admission, a decubitus 2 cm. in diameter appeared over the sacral area. This gradually increased in size. A purpuric area measuring 4 cm. in diameter appeared on the left side of the abdomen August 6. August 8 a small gangrenous area the size of a pea was noted on the right ala nasi. These areas gradually became more extensive, and August 11 several small purpuric spots were seen around the umbilicus and in the left groin. The patient died at 11:45 p. m. August 12, twenty-two days after admission and approximately seven months after the onset of the illness.

Laboratory Examination.—The urine was normal. Reactions to tuberculin (1:1,000), Schick, Wassermann and Kahn tests

were all negative. Sternal puncture was attempted without success August 5, eight days before death. It was not repeated because of the critical condition of the patient.

The results of differential counts are shown in the accompanying table. July 22 no malarial parasites were seen on the blood smear. July 27 marked anisocytosis and a few poikilocytes were evident. August 4 thrombocytes were practically absent. August 10 the erythrocytes appeared normal and no thrombocytes were seen in the preparation.

Necropsy (Gross and Microscopic).^{2a}—The body was 60 cm. long, which is normal for a baby of 4½ months. It weighed 3,580 Gm. The skin contained areas of hemorrhage of varying size, the largest 2 cm. in diameter, with ulceration. Deep purple staining material was observed immediately below the epidermis and in the deeper portions. Parasitic bodies were present in these areas, being especially numerous at the points of ulceration. The skull was not opened. The cisternal fluid was clear and colorless.

The thymus and mediastinal and bronchial lymph nodes appeared normal on gross inspection. The pleural cavities appeared normal. The lungs showed congestion and atelectasis. The pericardial sac and heart were essentially normal. The peritoneal cavity was normal.

The liver, which weighed 237 Gm. (normal, 175 Gm.), was firmer than normal, with capillary hemorrhages and passive congestion. Microscopic examination revealed fibrosis about the trinites, with numerous and prominent cells of the reticulo-endothelial system containing many parasitic bodies. There was a considerable deposition of brown pigment.

The spleen weighed 144 Gm. (normal, 16 Gm.) and was 11.9 cm. long. The surface was deep red and the cut surface firm and congested. There was extensive replacement of the lymph follicles by endothelial cells crowded by parasitic bodies and pigment. Although the reticulum was prominent, the trabeculae were not. The pancreas showed areas in which the acinar structures had undergone a fatty metamorphosis or

The mesenteric lymph nodes were enlarged and matted together. Microscopic examination showed replacement of the original structure except the capsule and reticulum by very large foamlike cells containing parasitic bodies. Some cells were multinucleated and others showed no nuclei and were probably at the point of rupture.

The kidneys weighed 38.5 and 36 Gm. (normal, 21 Gm.), were congested and showed petechial hemorrhages. Small gray

Fig. 4.—Section of bone marrow, oil immersion field ($\times 1,908$) showing the parasitic bodies. P, parasitic bodies.

Fig. 3.—Section of spleen under high power photomicrograph ($\times 1,600$) showing many endothelial cells containing the parasitic bodies. P, parasitic bodies.

replacement by foamlike cells which appeared to contain bodies suggestive of parasitic bodies.

In the intestine numerous petechiae were observed in the serosa, the vessels being injected. The mucosa was edematous, with hemorrhagic and ulcerated areas. Microscopic examination showed a dense infiltration of large cells containing parasitic bodies immediately beneath the ulcerated areas. The inflammatory reaction was mild. In the necrotic area was observed a mass of purple staining material similar to that noted in the skin and kidney.

and white areas were scattered throughout the cortex and medulla. Microscopic examination revealed collections of black or deep purple pigment in the vessels which showed intimal proliferation. The tubules showed degenerative changes, as evidenced by swelling and fatty infiltration of the lining cells, their lumens containing hyaline material and deep purple pigment.

In the adrenals, hemorrhagic and firm white areas were noted. The greater portion of the medulla and to a lesser extent the cortex were replaced by large clear pale staining cells with relatively small nuclei. These cells were largely filled with parasitic bodies rather than fat; however, many of the cortical cells showed evidence of fatty metamorphosis. Several areas of necrosis were found in the central portion of the gland.

In the bone marrow, endothelial cells containing parasitic bodies were frequently noted.

The parasitic bodies seen in sections of the skin, liver, spleen, pancreas, intestine, mesenteric lymph nodes, adrenals and bone marrow closely resembled the intracellular parasites described by Crumbine and Kessel. The organisms were found almost without exception in large endothelial cells. On examination with oil immersion, each body was found to consist of a central portion surrounded by a capsule or wall.

On first observation there appeared to be a rather marked similarity between the parasitic bodies and the Leishman-Donovan bodies of kala-azar. However, no distinct blepharoplast was observed, and the wall was thicker than the thin ectoplasmic membrane of parasitic bodies. The irregular arrangement of the chromatin material within the cytoplasm was more suggestive of a yeastlike body than of a protozoan cell.¹

COMMENT

In 1905 S. T. Darling at the Ancon Hospital, Canal Zone, spurred on by a statement of Sir Patrick Manson³ that kala-azar or an analogous disease might be found in America, made a special postmortem study

3. Manson, Sir Patrick, in a lecture on tropical diseases delivered at Chicago and cited by Darling.^{1b}

2a. Courtesy of Pathological Department, Dr. J. W. Lindsay, director.

relative to the presence of Leishman-Donovan bodies in the tissues of all patients dying of splenomegaly at the hospital. During a period of approximately two and one-half years, in which there were 33,000 admissions, Darling found three cases of a disorder seen to possess certain points of resemblance to kala-azar, viz. splenomegaly, irregular pyrexia, leukopenia, anemia, emaciation and chronicity. On examination of tissues in these cases a parasite was found which, while bearing some resemblance to the etiologic agent of kala-azar, had certain fundamental morphologic differences. To quote Darling's description, the disease was caused by a small round or oval micro-organism from 1 to 4 microns in diameter, a polymorphous chromatin nucleus, and achromatic spaces, all enclosed within an achromatic refractile capsule.

The micro-organism differs from the Leishman-Donovan body of kala-azar in the form and arrangement of its chromatin nucleus and in not possessing a rod. Believing the organism to be of a protozoan nature, Darling applied to it the name of *Histoplasma capsulatum* and called the disease in which it appeared to be the etiologic agent histoplasmosis.

In 1912 Da Rocha-Lima,⁴ after a study of tissues from Darling's cases, expressed the view that *Histoplasma capsulatum* was closely related to *Cryptococcus farciminosus*, the etiologic organism of epizootic lymphangitis of horses, a member of the group of fungi imperfecti belonging to the group Hyphomycetes. According to Meleney,⁵ Darling concurred with him in this conclusion.

DeMonbreun in 1933, working with cultures of the organism obtained in the case of Dodd and Tompkins, was able to accomplish much toward determining the exact classification of the parasite as well as throwing further light on its pathogenicity. During the course of his work he discovered that the organism could be cultured and grown in yeastlike and mycelial form. Experimentally producing the disease by the intravenous inoculation of monkeys (*Macacus rhesus*) he firmly established the fungus as the etiologic organism in histoplasmosis and demonstrated that the "pathogenic" or intracellular phase of the parasite is the yeastlike form.

As the result of his observations, DeMonbreun concluded that "although certain cultural characteristics of the organism are suggestive of those of the Endomycetales group of fungi, it seems best to retain for it the name *Histoplasma capsulatum* as given by Darling, until comparative cultural studies determine its logical classification," and he recommended that "to emphasize its relationship to the host cells . . . the present clinical term Histoplasmosis of Darling be changed to Cytomycosis of Darling."

Ciferri and Redaelli² have expressed the belief that the parasite "must be classified among the Blastospores sensu lato or the group . . ."

Since the disease was first . . . years ago, little has been written on the geographic distribution, mode of transmission and possible natural reservoirs. Darling said that its most likely origin was in Martinique or Panama, since two of his patients were Martinique Negroes residing in Panama. His third patient, a Chinese, had lived on the Isthmus for fifteen years prior to his death. The rapidly improving sanitary conditions of the Canal Zone, Darling felt, were responsible for its apparent disappearance from this

area. He prophesied, however, that histoplasmosis would be encountered in some part of tropical America "not yet disturbed by the sanitarian." The thought that it might be found on the North American continent he expresses in another writing:¹⁰ "New World disorder is bound to appear in Baltimore some day."

No writer except Darling has ever ventured an opinion as to the mode of transmission of the disease.¹¹ He expressed the opinion that it "may be transmitted by a suctorial insect or acarid, or the micro-organism may gain entrance to the tissues of the host through the intestinal tract." It should be stated that this quotation is taken from one of his earlier papers on histoplasmosis, written when he was under the impression that the causative organism was protozoan and similar to the Leishman-Donovan body of kala-azar. No other view on this aspect of the disease has been expressed in any of his subsequent writings.

Numerous attempts were made by Darling to determine whether the parasite was present in the water, insects and animal life (including monkeys) of the Canal Zone, but without success. Special examination and culture of the feces and material from the intestinal tract were equally unfruitful. The work of DeMonbreun, in which he was able to produce the disease experimentally in rhesus monkeys, suggests a possible reservoir of the disease in the tropics. The same worker was able to achieve similar results in mice and puppies by the use of much larger amounts of the broth suspension of the parasite than that used in the inoculation of the monkeys.

Because the disease was recognized during life in only one of the seven cases reported, little has been written on its therapy. Dodd and Tompkins used symptomatic and supportive treatment, as they felt that "treatment for the overwhelming parasitic invasion of the body was problematical and seemed almost hopeless."

The only possible therapeutic suggestion for histoplasmosis which we have found in the literature is that contained in a report by Nègre and Bidre⁶ of 1911 of a case of human epizootic lymphangitis. In this instance one dose of 0.6 Gm. of arspenamine "brought about a speedy and complete cure." Since some writers have maintained that there is similarity between *Cryptococcus farciminosus*, the etiologic organism of epizootic lymphangitis, and the parasitic agent of histoplasmosis, one of the arsenicals might theoretically be indicated in treatment of the latter.

The history and clinical picture which our patient presented on admission were somewhat similar to those noted by Dodd and Tompkins for their patient, also an infant, although their patient's course was much shorter. From the point of view of chronicity, our patient's condition resembled more closely that described for adults. Our hemograms, characterized by leukopenia, decreased platelets, severe anemia and a moderate number of monocytic cells, approached somewhat, except for the leukopenia, the hematologic picture noted by Dodd and Tompkins. Because we felt that we were dealing with primary anemia, no attempt was made to examine blood smears by the supravital technic for parasites. We found no "parasitic inclusions" in our smears stained with Wright's stain, as those workers stated that they did in their case.

The postmortem appearances in the case we are reporting agree closely with those described by Darling and by Riley and Watson, namely an overwhelming parasitic invasion of all the body tissues, including the

4. Da Rocha-Lima, H., cited by DeMonbreun.²

5. Meleney, H. E., cited by DeMonbreun.²

6. Nègre and Bidre, cited by Riley and Watson.³

bone marrow, which involved especially the large mononuclear cells. On gross examination, however, we noted no pseudogranuloma of the lungs as described by Darling and said by him to be the "chief anatomic difference" between kala-azar and histoplasmosis.

For some time we regarded the case under discussion as one of infantile kala-azar, the history, clinical picture, hemograms and gross pathologic picture fitting in closely with those described by Scott and Li⁷ in their series of 100 cases and with those reported by other writers. Although our patient had no history of a contact with any one suffering from the disease or coming from a country in which it is endemic, the fact that a case⁸ of kala-azar was said to have been discovered near the home of our patient some years before made us speculate as to the presence of an endemic focus of that disease in this area. The morphologic picture of our parasite was somewhat atypical when compared to that of Leishman-Donovan bodies seen in tissue sections from countries where kala-azar is endemic since we were never able to demonstrate the chromatin rod or blepharoplast.

We conjectured as to whether our inability to obtain a clearer morphologic picture by the employment of some parasitic stain such as Leishman's might not be due to the fact that the nature of the disease was not suspected at autopsy. The specimens of tissue taken for microscopic examination were fixed in 10 per cent solution of formaldehyde, which is the routine procedure at our laboratory. Our slides were submitted to a number of parasitologists and pathologists experienced in the field of tropical medicine, the majority of whom concurred with us in our diagnosis of kala-azar.

However, further study of our sections and persistent failure to demonstrate in any of our parasites a chromatin rod, together with the presence in some of our organisms of a capsule, made us question somewhat the validity of our diagnosis. These facts and the opinion of Dr. Henry E. Meleney,⁹ who had examined some of our sections, made us suspect that we were probably dealing with a case of histoplasmosis and made the diagnosis of kala-azar no longer tenable in our minds, and we felt that our tissue sections no doubt demonstrated the "pathogenic," or intracellular, phase of the parasite.

In conclusion, the history, clinical picture and laboratory and pathologic examinations lead us to believe that this was a case of histoplasmosis of Darling. Because of the rarity of the disease some of the slides have been placed on file at the Army Medical Museum, Washington, D. C., where any one interested may see them.

We should like to stress the advisability of considering this disease in the differential diagnosis of any obscure case of splenomegaly, especially if the splenomegaly is associated with intermittent pyrexia, cachexia and leukopenia. Supravital stained blood smears and possibly bone marrow or splenic puncture might prove valuable diagnostic aids.

SUMMARY

In a case of splenomegaly and hepatomegaly with anemia in an American born girl aged 11 months, the history, clinical picture and course, as well as the post-mortem examination, supported the diagnosis of histoplasmosis of Darling. It is believed that this is the fourth case to be reported in the United States and the eighth in medical literature.

Clinical Notes, Suggestions and New Instruments

TWO CASES OF ACUTE HEMOLYTIC ANEMIA WITH AUTO-AGGLUTINATION FOLLOWING SULFANILAMIDE THERAPY

WILLIAM ANTOPOL, M.D.; IRVING APPLEBAUM, M.D., AND
LESTER GOLDMAN, M.D., NEWARK, N. J.

CASE 1.—A white man aged 34 complained of a "grippy" feeling for two days. Two years previously he had a subtotal gastrectomy performed for gastric ulcer. On the third day of his present illness, Aug. 27, 1938, the temperature rose and signs of consolidation were found at the base of the right lung. He was admitted to the hospital on that day with a temperature of 104.4 F., a pulse rate varying from 85 to 100 a minute and a respiratory rate of 25 a minute. An x-ray examination confirmed the diagnosis of consolidation of the right lower lobe. The sputum contained pneumococci which could not be typed with the available thirty-two type serums. Fifteen cc. of 5 per cent neoprontosil was given that day. Since no specific therapy could be used, it was decided to give repeated small

Fig. 1 (case 1).—Response of the blood to transfusions and neoprontosil.

transfusions. These were done August 28 and 31 and September 3 without any improvement. The blood was found to belong to group O. No difficulty was encountered with blood typing procedures at these times. Daily examination of the sputum showed the presence of pneumococci, which remained unidentifiable except on August 29, when type XV pneumococcus was obtained from the peritoneal exudate of a mouse injected with the sputum. Type specific rabbit serum (420,000 units) was given without any beneficial response. This organism was not found again in the sputum. The results of lung puncture and frequent blood cultures were negative. Starting September 1 and continuing through September 3, 160 cc. of neoprontosil, equivalent to 8 Gm. of sulfanilamide, was administered intramuscularly. The level of sulfanilamide in the blood in the morning specimens was never above 3.5 mg. per hundred cubic centimeters total. September 4, slight jaundice and hemoglobinuria were noted. This increased progressively, as did the urobilinogen in the urine. September 6 the icteric index was 83, the direct Van den Bergh reaction was positive with 4.7 mg. of bilirubin in 100 cc. of blood, and the hemoglobin content was 56 per cent. The fragility of the red blood cells remained normal. At this time it was decided to give another transfusion.

When the patient's blood was typed for the transfusion, the unwashed red cells were found to be intensely agglutinated by both group A and group B as well as by group O serums,

From the Laboratories and the Medical and Pediatric Services of the Newark Beth Israel Hospital.

ACUTE HEMOLYTIC ANEMIA—ANTOPOL ET AL.

despite the fact that the patient belonged to group O. This had not occurred with his blood on the occasion of his previous three transfusions. The agglutination disappeared in all three suspensions after incubation at 37 C., indicating group O. The agglutinins could be absorbed from the patient's serum by centrifuging a cooled suspension of red cells and serum. After

intrinsic stomach factor were administered in addition to the transfusions. After five days the hemoglobin began to increase and recovery, so far as the blood changes were concerned, was prompt. The patient then made an uneventful though prolonged recovery from the pneumonic process.

Auto-agglutination at room temperature at times made it impossible to count the red blood cells without warming the counting chamber during the procedure. The auto-agglutination of the red cells is reflected in the blood smears (fig. 2), in which the erythrocytes were clumped and unevenly distributed during the period in which the phenomenon was evident. The early smears, as well as those obtained during convalescence (fig. 3), showed a comparatively uniform distribution of the red blood cells.

CASE 2.—A white boy aged 5 years was admitted to the Newark Beth Israel Hospital with a diagnosis of acute anemia. Five days prior to admission he complained of severe sore throat with a temperature of 104 F. Two days prior to admission he was given 90 Gm. of sulfanilamide over a period of thirty-six hours. The following day there developed an acute anemia and gray buccal patches. Laboratory examination at that time showed evidence of a moderately severe acute hemolytic anemia (fig. 4) with hemoglobinuria.

Fig. 2 (case 1).—Blood smear during hemolytic phase with auto-agglutination, showing intense clumping of red cells.

this procedure had been repeated several times, the supernatant fluid remained free of the agglutinins. Because of the auto-agglutinability at lower temperatures, the blood transfusions were given by the direct Lindemann method. There were no untoward transfusion reactions.

Fig. 4 (case 2).—Response of the blood to transfusions and sulfanilamide.

On admission his blood was typed for transfusion, at which time the erythrocytes were strongly agglutinated by both A and B serums, suggesting group AB. It was found that his red cells were also agglutinated by his own serum at room temperature. All these agglutination phenomena disappeared after incubation at 37 C. and his blood was found to belong to group O. This blood was identical in its reactions with that of case 1. He was promptly given 350 cc. of blood and an infusion of 5 per cent dextrose in saline solution. Blood cultures taken at this time were sterile. Because of our experience in case 1, a favorable prognosis was given despite the apparent ominous appearance of the patient. He was given daily transfusions for a period of four days in amounts varying from 300 to 350 cc. On the second day slight jaundice developed which gradually subsided.

The erythroid picture remained constantly low, despite the daily infusion of blood, until the fifth day, when it showed a prompt rise. Following this, recovery was rapid and uneventful (fig. 4).

SUMMARY AND CONCLUSIONS

1. In two cases of acute hemolytic anemia following sulfanilamide therapy, there was intense auto-agglutination.
2. Auto-agglutinins as a possible source of error should not be overlooked in typing the patient's blood.
3. Direct transfusions of compatible blood can be administered without danger if precautions are taken against cooling of the blood.

201 Lyons Avenue.

Fig. 3 (case 1).—Blood smears during convalescence, showing even distribution of red cells.

The anemia was rapidly progressive (fig. 1) and persistent and required eight blood transfusions, totaling 2,550 cc. of blood in seven days. The course was that of an acute hemolytic anemia. During the acute period leukocytosis was pronounced, at one time reaching 56,000 per cubic millimeter, with a moderate number of myelocytes and an occasional myeloblast. Because of the possible bearing the subtotal gastrectomy might have had on this condition, iron, liver, hydrochloric acid and

Special Clinical Article

THE AUTOMOBILE AND THE FRACTURED SPINE

CLINICAL LECTURE AT ST. LOUIS SESSION

H. EARLE CONWELL, M.D.

BIRMINGHAM, ALA.

The relation of the automobile accident and the fracture—whether it is a fracture of a vertebra or of any other bone in the body—involves not only possible permanent injury but life as well. The proper procedures in the early history of a fracture and the immediate recognition of all local and general pathologic change are important. It is the duty of the medical profession to make the public conscious of the thousands who today are permanently disabled by automobile accidents, many because of carelessness in first aid. The public must be taught the importance of first aid. Without a doubt certain lives ended in the past by motor vehicle accidents

Fig. 1.—A, incorrect way of transporting a patient with an injured spine; severe damage can be done by carrying the patient in this manner. B, a proper method of transporting a patient with an injured spine when no stretcher is available. (A and B are from Jones, R. Watson: *J. Bone & Joint Surg.* 10:12 [March] 1928.) C, a simple type of litter placed over a hospital cart. Note the handles which run through each side of the litter. When not in use this litter can be folded and stored in a very small place. Instead of the handles any round pieces of wood can be used. D, patient on the litter before being lifted off the cart. This type of stretcher is very applicable in the case of injuries to the back. The patient should be carried with his face down.

could have been saved and permanent disabilities prevented by proper first aid. Even though certain groups, one being the automobile manufacturers, have introduced many safety first methods and devices, thereby lowering the number of accidents, such accidents can never be entirely eliminated, mainly because of the element of human carelessness.

The magnitude of the damage being done by automobile accidents in the form of fractures and permanent disabilities of the human body can be partly realized by reference to certain figures.¹ In the United States for the past few years there has been annually an average of one and one-half million people injured by the automobile. In 1937 there were approximately 39,500 people killed by motor vehicles—an all time high. In the last thirteen years more people in the United States have

died as the result of automobile accidents than were killed in all American wars. In 1938 there was a reduction in the number of deaths from automobile accidents to 32,400. This was the first time in six years that there had been a reduction in fatal automobile accidents and only the second time since the automobile became a factor in American life that the total of traffic deaths in the United States was lower than in the preceding year. To the National Safety Council, which celebrated its twenty-fifth anniversary last year, must go most of the credit for this reduction.

Through an authoritative investigator² it has been estimated that in the United States 13,000 spines were fractured in 1937. Since industry today, through its safety first measures, is reducing all injuries and thereby reducing the number of fractured spines, but since, on the other hand, automobile injuries are on the increase, it can be estimated that of the 13,000 fractured spines approximately 8,000 were caused by motor vehicles. The National Safety Council² stated that 1,160 people died in 1937 as the result of fractured spines received in motor vehicle accidents. These estimates give approximately one fractured spine every hour during

the twenty-four hours of the day as the result of motor accidents, of which three can be expected to cause death. It is impossible to estimate the percentage of permanent disabilities resulting from the nonfatal fractures.

Too frequently are superficial examinations made, the result being that fractures of the spine are often overlooked. Occasionally a definite fracture of two or more adjacent vertebrae with one or more normal vertebrae between them may occur from a single accident. Such conditions make it imperative that the surgeon examine the entire spine for fractures.

With spinal fracture there is always a backache of varying severity. Frequently there is no deformity of the back. Many fractures of the spine are not recognized because the patient is able to walk after the accident. The patient often underestimates his injury, frequently stating that he has a "kink" in his back and that the disability is of no importance. Such injuries, however, usually become more painful as time goes on and eventually medical advice has to be sought. Patients have walked into the

office several days after an automobile accident, suffering from backache, and on doing physical and x-ray examinations I have found definite fractures of the spine, frequently of the anterior compression type. Regardless of the insignificance of the injury, whether it is direct or indirect, one should feel suspicious of a spinal fracture when pain in the back is present. It is important to take an oblique roentgenogram in certain cases as well as the lateral and anteroposterior views.

To the lay mind and unfortunately to many medical minds as well, a broken back or neck is a broken back or neck and as such is a dreadful accident which results in sudden death or complete and permanent paralysis below the level of the lesion, with the patient relegated to permanent total disability. This gloomy point of view is the heritage of the days before the introduction of the x-rays, when only the severe fracture dislocations of the spine with extensive damage to the spinal cord

2. Davis, A. G.: Personal communication to the author during November 1938.

Read in the Surgical Division of the General Scientific Meetings at the Ninetieth Annual Session of the American Medical Association, St. Louis, May 16, 1939.
1. National Safety Council, Chicago: Personal communication to the author during January 1939.

were recognized as spinal injuries. At the present time it is known that more than one half of the fractured spines are not accompanied by paralysis and that with adequate treatment most patients may be expected to recover and return to their former occupations.³

It should be emphasized that fractures of the spine are not necessarily dangerous on account of the skeletal injury but are dangerous to life when associated with damage to the spinal cord or other visceral or skeletal injuries. On the other hand, it is to be emphasized that skeletal injury may cause prolonged disability if proper treatment is neglected. Pressure on the cord is often effectively relieved by early reduction and immobilization, which tend to restore and maintain the normal diameter of the spinal cord. In certain cases paralysis clears up spontaneously, but anatomic lesions of the cord may be made permanent by irreparable injury to the cord itself or by bony pressure to the cord, and when such conditions are present consultation with capable surgeons should be requested.

Many types of vertebral fractures result from automobile accidents. Only the most common type, the compression fracture, will be discussed. More than 50 per cent of all fractures of the vertebrae are of this type, and it has been my experience that the incidence is greater for fractures following

More than 70 per cent of anterior compression fractures occur at the dorsolumbar junction. Most such fractures are received by suddenly sitting down on the buttocks or encountering forceful pressure from above on the shoulders, so that the shoulders are compressed forward and a "jackknifing" position of the body is produced. Such trauma can easily happen when an automobile is turned over or an occupant is thrown from the car. Another type of accident which frequently causes an anterior compression fracture is the hitting of a speed breaker or similar obstructions in the road so that the occupant is thrown up, the force producing either a fracture of a cervical vertebra by the head striking the roof of the car or a compression fracture low in the spine by the sudden downward force directed on the buttocks.

Davis² has said:

I have made no other tests in relation to the automobile accident as a cause of compression fractures of the spine but have often referred to the fact that a person driving a car at 40 or more miles an hour thinks of the car as representing the velocity, while of course the torso is under the same velocity. The torso is usually braced somewhat by the legs, and in the sitting position the solid weight of the chest, shoulder girdle and head is thrown forward at the time of impact. This affords an explanation of the "whiplash" or "jackknifing" occurring at the dorsolumbar junction. It also explains the dislocations in the cervical part of the spine, where the weight of the head is involved in the "whiplash" action; i. e., the patient is sitting with the buttocks forward in the seat and the shoulders braced against the upper part of the seat, and the weight of the head continues its momentum on the torso at the time of impact.

A compressed vertebra may be and usually is impacted so firmly that considerable force is necessary to loosen the impaction and restore the normal height of the vertebral body. The strong anterior common ligament, which is continuous across the disks and vertebral body, usually remains intact, although it may be stripped up from the anterior surface of the body. Davis⁴ has shown that by remaining intact the anterior

ligament enables the surgeon to correct the deformity by hyperextending the spine with little fear, in most instances, of damaging the cord or pulling the vertebrae apart, except when there is a definite fracture or a fracture dislocation in the posterior arc. Occasionally in such injuries when the hyperextending force continues to act the vertebra above is displaced forward or forward and to one side on the vertebra below. When this occurs there is a fracture of the posterior arc or of the articular facets and the spinal cord tends to be crushed between the posterior border of the body of the vertebra below and the posterior arc of the vertebra above the point of fracture. In rare instances there

Fig. 2.—A, the modified Herzmark hyperextension frame in use. B and C, ambulatory plaster fixation for anterior compression fractures in the dorsal and lumbar regions. Note the maintenance of hyperextension, as shown in the side view. This type of cast can be worn during the whole convalescence, or a Taylor back brace or its modification can be substituted in the course of convalescence. (B and C are from Key, J. A., and Conwell, H. E.: *The Management of Fractures, Dislocations and Sprains*, ed. 2, St. Louis, C. V. Mosby Company, 1937, p. 320.)

may be a tearing of the interspinous ligaments or a splitting of the spinous process with subluxation or even dislocation of the articular facets, injuring the spinal cord and nerve trunks.

In certain spinal injuries there is a variable amount of damage to the intervertebral disks⁵ in the vicinity of the fracture. These disks may be injured and protrude anteriorly or into the cartilage plate of the vertebrae above or below, or they may rupture into the

spinal canal, causing pressure on the cord. Batts⁶ states that "permanent protrusion of the disk substance may occur in any direction." Of fifty spines examined by him post mortem, 20 per cent showed protrusion of the disk into the bodies of the adjacent vertebrae, 16 per cent rupture of the nucleus pulposus posteriorly into

Fig. 3.—*A*, Lateral view showing marked anterior compression fracture of the first lumbar vertebra. *B*, view taken immediately after reduction by hyperextension of the spine as described in the text. The contour of the vertebra is restored. The patient had an uneventful recovery, with good functional results.

the spinal canal and 6 per cent anterior protrusion. Batts further states that "the terms 'protrusion of the disk' and 'rupture of the nucleus pulposus' are not used interchangeably. Protrusion may refer only to the annulus fibrosus, in which there is no solution of continuity, while a rupture of the nucleus pulposus refers to an actual break in the annulus or the cartilage plate with extrusion of the nuclear contents." He concludes that "rupture of the nucleus pulposus is a common lesion. It may occur in any direction: However, as commonly referred to it is usually taken to mean a rupture posteriorly only with protrusion into the spinal canal." I have observed ruptures of the nucleus pulposus into the cartilage plate which did not show up in roentgenograms immediately after the injury but several weeks or months later were revealed by lateral roentgenograms taken on account of backache developing after an apparent cure.

The deformity present in an anterior compression fracture of the spine should be corrected, provided the general condition permits. Several technics for carrying out hyperextension with or without traction have been described, one being the method of Davis.⁷ I use a modified Herzmark frame on which the patient is placed after admission to the hospital as soon as all necessary treatment for shock has been given. The patient is placed on the frame with the frame in full extension. The angle for bringing about convexity of the spine is placed opposite the deformity of the spine. The turnbuckle on the frame is gradually tightened, which convexes the frame more and more, thereby bringing about hyperextension of the body. The hyperextension should be produced gradually, and usually at the end of fifteen or twenty minutes full correction of the deformity is obtained. Correction of the deformity should be controlled by lateral roentgenograms. All these procedures should be done after the patient has been given sufficient opiates to make him comfortable. I have not found it necessary to give general anes-

thetics; however, in certain cases I have used avertin with amylene hydrate. At the limit of hyperextension the patient usually feels tension in the abdominal muscles, and physical examination will usually disclose disappearance of the prominence of the spine at the site of the fracture. In certain instances it may be necessary to apply head and foot traction, combining this with hyperextension.

I have seen paralytic ileus develop; this becomes a major surgical factor and demands immediate attention. None of our cases have proved fatal, but there are reports of death from this complication. I feel that too severe manipulative procedures or the too early application of tight body casts is a predisposing factor.

After the reduction the patient may be allowed to remain on the frame for a few days, and the plaster cast may then be applied. In certain instances antero-posterior plaster shells may be used. If a cast, circular or shell-like, is used, the patient's back should be kept in a hyperextended position while it is being applied.

If the economic condition will permit, I prefer to have the patient remain on the frame for five or six weeks and then to apply a snug-fitting body cast, keeping the patient's back in a hyperextended position and placing the plaster high up in front in order to retain the hyperextension of the spine. This cast is worn for five or six weeks, and then a properly fitted Taylor back brace is applied and worn until roentgenograms show complete restoration of the crushed vertebra.

I have had several patients in whom renal stones developed, and in some they developed with startling promptness after the injury. In two the stones occurred bilaterally. It has been well known for years that a fracture of the vertebra or multiple fractures of the

Fig. 4.—*A* and *B*, normal anteroposterior and lateral views of an injured back. On account of persistent pain in the back and other physical evidence suggestive of a fracture of the spine, further investigation was carried out and an oblique roentgenogram was made. *C*, oblique view, showing a fracture in the posterior arc.

body may be followed by the formation of renal calculi. The earliest report of such a case in English literature was contributed by Costello⁸ in 1833. He stated that Earle⁹ had described several cases of lithiasis in which he attributed the condition to a subacute inflammatory condition of the kidneys induced by injuries to the lumbar region. I have no specific explanation for the occurrence of renal stones in association with spinal

injuries. I¹⁰ reported a series of 100 cases of anterior compression fractures of the spine without cord injury, in eight of which renal stones developed. Oehlecker¹¹ says that "the blood clot which accompanies or follows an injury to the kidney does not alone suffice to explain the formation of calculi, since the clot is often changed or even absorbed while the stone forms, but that there must be in addition a disturbance of the colloid-crystalloid equilibrium of the urine with resultant precipitation of the urinary salts about a central nucleus or framework of red blood cells or fibrin in the clot." Goldstein and Abeshouse¹² state: "there are many factors concerned in the formation of renal calculi after injuries of the vertebrae and cord. The most important consideration is the condition of the kidney before and after the accident. . . . In some cases the formation of calculi is dependent on a primary intrinsic lesion of the kidney, i. e. a rupture or tear of the renal parenchyma with extravasation of blood into the renal pelvis which occurs at the time of the injury to the vertebrae and cord."

It is not within the province of this paper to discuss in detail the estimation of the percentage of disabilities due to spinal fractures resulting from automobile or other accidents. I know, however, that many so-called spinal injuries following automobile accidents are grossly exaggerated by the patient. Mock¹³ states that "medicolegal evils undoubtedly started when medicine first went into court to prove or disprove sanity, responsibility for personal injury and the like. The limits of ethical legal practice are broad, those of the science of medicine more restricted. Physicians are by training experts in the science of medicine, but in the art of medicine, judgment, experience and integrity are factors and may lead to a divergence of opinion among physicians." Stern¹⁴ states that "the mental attitude of the patient greatly influences his ability to carry out the work which his disability, age and occupation should warrant his performing. Malingering and deliberate exaggeration must always be summarily condemned, but genuine psychoneurosis must at least be viewed in a sympathetic manner. . . . An examining physician must at all times be on his guard against the obvious fallacy of calling every hidden and unexplained condition a neurosis or exaggeration, and it is my opinion and constant practice never to make a diagnosis of neurosis until repeated examinations have fully demonstrated the lack of objective corroborative evidence of the actual existence of disability. Often actual disability of a minor grade and psychoneurosis coexist."

I feel that the psychoneurotic tendency of the patient with a fractured spine is an individual problem and that he should be given a thorough explanation of his condition by his physician, with assurance that he has an excellent chance to recover normal function. Confidence of the patient in the physician is essential.

CONFERENCES ON THERAPY

TREATMENT OF POISONING

NOTE.—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors.

DR. McKEEN CATTELL: The treatment of poisoning in man offers problems to the physician which at times will call on all the resources at his command. In the first place the diagnosis is apt to be difficult, and in addition to the physical signs and symptoms the physician will often need to call on his ability as a detective. Further, the conditions under which treatment must be employed are likely to be difficult. Quick decisions are necessary, often in the midst of a much disturbed atmosphere. Finally, while many of the general principles of treatment are well worked out, many difficulties arise when it comes to the choice of a specific antidote and the amount which shall be administered, and the literature on the subject gives one very little help.

It is hoped that during the present session we shall be able to crystallize the more important information regarding drug therapy in some common forms of poisoning.

We are fortunate in having Dr. Helpern here today. He will tell us something of the sort of problems he has met with in his wide experience in the Medical Examiner's Office, and perhaps give us some points in the recognition of poisoning by different drugs.

DR. MILTON HELPERN: In the year 1937, 898 persons in New York City died of poisoning. This incidence represents 17.2 per cent of the total of 5,221 violent or unnatural deaths¹ investigated by the Office of the Chief Medical Examiner during that year, or 1.2 per cent of the total of 77,465 deaths from all causes in the entire city. These 898 cases of fatal poisoning do not include 460 deaths from acute and chronic alcoholism and 110 deaths from various anesthetics.

Accurate statistics as to the number of persons poisoned who did not die are not available. A physician who treats a patient in private practice for poisoning resulting from accident or an attempt at suicide is not required to report the case to the authorities if the patient does not die. I do not know of any central bureau where all cases of nonfatal poisoning observed in private and hospital practice are reported. Despite this lack of complete statistical information concerning the nonfatal cases of poisoning, the 898 fatal cases and the records of successfully treated cases in the many hospitals of the city indicate a very large total number of poisonings and a clinical problem of considerable magnitude.

The accompanying tables are condensed from the latest available (1937) Annual Report of the Chief Medical Examiner of New York City and list the different types and the incidence of fatal poisonings as they occur in a large cosmopolitan city.

All violent deaths, including those caused by poison, are classified as homicidal, suicidal or accidental. The individual poisons causing death and their frequency

1. A total of 16,315 deaths were investigated by the Office of the Chief Medical Examiner in 1937.

are also listed in each classification. Violent deaths are designated as homicidal or suicidal only when the necropsy and circumstances surrounding the case warrant such a designation. In some instances of fatal poisoning, as well as in other forms of violent death, the circumstances surrounding the death cannot be ascertained and the qualification of the death must remain undetermined. Some of these undetermined cases are probably suicidal and some possibly homicidal in nature. To simplify the tables, the accidental and undetermined cases have been grouped together.

Incidence of Fatal Poisonings in New York City in 1937 *

* Abstracted from Annual Report of the Chief Medical Examiner.
† Exclusive of 460 deaths from acute and chronic alcoholism and 110 deaths during one or another form of anesthesia.

There were 350 homicidal deaths in 1937 and less than 300 in 1938. Comparing this number with 569 in 1931, 565 in 1932 and 524 in 1933, a steady sharp drop in the number of homicides since 1933 is noted, coinciding with the repeal of the prohibition laws. Only ten homicides in 1937 were caused by poisoning, or slightly less than 3 per cent; about the same number of cases of poisoning homicides have occurred each year since 1918 despite considerable variations in the total number of homicidal deaths. Eight of the ten homicidal poisonings were caused by carbon monoxide in illuminating gas and were generally associated with the suicide of the perpetrator, usually several deaths occurring in one family. Illuminating gas has been utilized to kill

intoxicated persons apparently for purposes of collecting insurance. Such homicides may be carried out with considerable ease in a room equipped with gas fixtures, the scene being arranged to suggest an accidental or suicidal death. Chloral hydrate has been added secretly as "knock out drops" to food or drink to render a person helpless in order to facilitate robbery or rape and it may cause death. Cyanide has been forcibly fed to a helpless victim by a psychopathic individual.

In 1938 there were two homicidal arsenic poisonings perpetrated by a feeble-minded girl who placed rat poison in coffee which the victims drank. Clinically these cases were not recognized as arsenic poisoning but were diagnosed as food poisoning and botulism. Homicidal poisonings are rarely diagnosed correctly during life.

There were 1,195 suicidal deaths in 1937. Of these 561, or 47 per cent, were caused by one or another form of poison; 428, or 76 per cent, of the suicidal poisonings resulted from the inhalation of carbon monoxide. Twenty-six persons committed suicide by ingesting cyanide, usually in the form of the sodium salt. This poison is taken by those who have access to it, photographers, chemists, jewelers. Sometimes the cyanide is dissolved in whisky. Persons who have taken cyanide are usually found dead or die before medical aid can be given. Not infrequently, friends or relatives of the deceased person attempt to disguise the true nature of the death by removing all traces of poison and suicide notes from the vicinity of the deceased, offering information which might lead an incautious medical examiner to attribute death to natural causes.

There were twenty-five suicides of persons who ingested large amounts of various barbiturate preparations. Such suicidal poisonings are definitely on the increase, usually occurring in persons who have available large quantities of various barbiturate compounds, prescribed as medication for disturbed mental states, insomnia or nervousness. The very condition which the medication is supposed to alleviate may prompt the patient to take a suicidal dose of the remedy, usually the contents of a whole bottle of tablets of phenobarbital, barbital, nembutal, amytal, medinal, dial, allonal or whatever preparation happens to be in vogue at the time.

In 1937 there were twenty suicidal poisonings caused by ingestion of phenol compounds, eighteen of lysol (saponated solution of cresol) and two of phenol. In 1932 there were forty-three lysol deaths and two caused by phenol.

Mercuric chloride caused death in twelve suicides and arsenic in seven, the latter being accomplished by the ingestion of arsenic trioxide in rat poison. There were three cases of phosphorus poisoning. Yellow phosphorus is an ingredient of roach paste, in which it can be detected by its characteristic odor.

Inorganic corrosive poisons are ingested with suicidal intent. Thus there were ten deaths from the ingestion of strong hydrochloric acid and one from nitric acid. The corrosive action of concentrated hydrochloric acid on the stomach mucosa is very severe and presents a striking gross picture. The mucosa becomes thickened and exhibits an intense brown and black discoloration. There were five corrosive poisonings caused by strong ammonia and five by sodium fluoride, which is the toxic ingredient in the blue roach powder so extensively and sometimes carelessly used by insect exterminators. Iodine swallowed in the form of the tincture caused

TREATMENT OF POISONING

495

four suicidal deaths. One case of poisoning was caused by swallowed lye. In many of the corrosive poisonings the regurgitation and inhalation of the corrosive may cause an asphyxiating laryngeal edema and a severe aspiration bronchopneumonia.

There were six cases of suicidal morphine poisoning. In some instances huge doses, as much as 20 or 30 grains, were injected intravenously. In other cases the drug was taken by mouth. Nitrobenzene, available in shoe dye, caused death in two cases; ingested chloroform also caused two deaths.

In the group of 327 accidental poisonings and those in which the circumstances are undetermined, the inhalation of carbon monoxide occurring in illuminating gas, motor exhaust fumes and coal gas is responsible for 215, or 65 per cent, of the total.

There are forty-one deaths of chronic heroin and morphine addicts. It is difficult to be certain that death was due to an overdose of the drug in all these cases, as these addicts have developed a marked tolerance to large doses of heroin or morphine by long habituation. Accidents may occur with injection of large doses of the drug after a period of withdrawal during which time tolerance may have diminished or disappeared. The cause of death in narcotic addicts is not easy to determine. Many narcotic addicts die of intercurrent disease which may be related or unrelated to their addiction. For example, since September 1933 more than 100 fatal cases of artificially acquired estivo-autumnal malaria in heroin addicts using the intravenous route for injection of the drug have been examined post mortem in the Office of the Chief Medical Examiner. Other addicts die of sepsis and tetanus from infected needle punctures. Death from chronic morphine and heroin poisoning can be established only after complete autopsy and chemical examination.

There were twenty-one deaths associated with the therapeutic administration of arsphenamine and neoparsphenamine for the treatment of syphilis. The pathologic picture varies; one encounters dermatitis exfoliativa, myelo-encephalorrhagia, acute yellow atrophy of the liver, aplastic anemia and occasionally, in deaths occurring soon after a single injection, no characteristic lesion.

Eight deaths from methyl alcohol poisoning are listed. These cases occur sporadically and were much more numerous during the days of prohibition. An indigent intoxicated person may purchase wood alcohol as such and then drink it. Other cases result from the drinking of an alcoholic beverage called "smoke," a cloudy liquid made by mixing water with "solid alcohol," a substance which contains methyl alcohol and is used for heating purposes. Persons who imbibe this beverage are alluded to as "bottle babies" and many such habitués seem to survive its immediate toxic effects for long periods. There were seven deaths from barbiturate poisoning in which the circumstances could not be definitely determined. Most of these were probably suicidal. There were three accidental fatal arsenic poisonings. Accidental metal poisonings are apt to occur in young children and creeping infants who are carelessly allowed access to rodent killing arsenic preparations or insecticides containing yellow phosphorus; these substances may be smeared on or mixed with food and placed in various parts of the home, where they are accessible to children. Some children eat lead paint off toys, chairs and metal cribs and die of acute lead poisoning. The single case of chronic radium poisoning occurred in a person who was formerly a painter of luminous

watch dials, who, while engaged at this occupation over a period of time, ingested minute amounts of radioactive material in the paint during the process of pointing the paint brush in the mouth. The swallowed radioactive material accumulated in the body of the victim, especially in the bones, causing a variety of ill effects. The etiology, symptomatology, pathology and toxicology of occupational radium poisoning were first described by Martland² and his associates in 1925 and 1926 and Martland has ably reviewed the entire subject in subsequent articles.

CARBON MONOXIDE POISONING

Carbon monoxide poisoning occurs much more frequently than all the other forms of poisoning combined. It has already been pointed out that eight out of ten homicidal poisonings were caused by carbon monoxide; 428, or 76 per cent, of the 561 suicidal poisonings and 215, or 65 per cent, of the 325 accidental and undetermined poisonings were caused by the inhalation of this gas. Illuminating gas was the source of the carbon monoxide in all of the homicidal cases and in 419 of the 428

suicidal cases. In the remaining nine suicidal cases the source of the carbon monoxide was automobile motor exhaust fumes.

The peak year for suicidal carbon monoxide poisoning was 1932, when there were 664 cases out of a total of 1,609 suicides. Since then there has been a gradual drop in the number of suicides and a corresponding drop in the number of suicides caused by carbon monoxide. The inhalation of carbon monoxide in the form of illuminating gas continues as the most common method of committing suicide. Of the 215 accidental and undetermined carbon monoxide poisonings, 178 resulted from the inhalation of illuminating gas, thirteen from motor exhaust fumes and twenty-four from coal gas escaping from defective stoves and flues. The number of accidental and undetermined carbon monoxide asphyxiations is considerably less than it was a few years ago. The peak year was 1926, when there were 825 such cases recorded. In 1925 there were 631, in 1927 634, and then a steady decrease up to 1937. Since 1932, the peak year for carbon monoxide suicides, the incidence of carbon monoxide deaths has dropped in both the suicidal and accidental categories.

2. Martland, H. S.; Conlon, Philip, and Knaf, S. P.: Some Unrecognized Dangers in the Use and Handling of Radioactive Substances, *J. A. M. A.* 85: 1769 (Dec. 5) 1925. Martland, H. S.: Occupational Poisoning in Manufacture of Luminous Watch Dials, *ibid.* 92: 466 (Feb. 9), 552 (Feb. 16) 1929; Occurrence of Malignancy in Radioactive Persons, *Am. J. Cancer* 15: 2435 (Oct.) 1931.

Accidental carbon monoxide asphyxiations may be caused by defective gas fixtures and appliances and may also result from carelessness on the part of an individual. For example, an elderly or a drunken person goes to the stove, turns on the gas and then forgets to light it. He may then seat himself near the stove waiting for a pot to boil and is rapidly asphyxiated.

In most cases of carbon monoxide poisoning the diagnosis is easy or obvious. The victim is discovered dead or alive in a gas filled room with one or more of the gas jets turned on.

If the victim is alive, he is removed from the poisonous atmosphere and various measures are employed to resuscitate him. In some cases recovery takes place, while in others there is a fatal outcome despite the most energetic attempts at restoration.

An important thing to remember about carbon monoxide poisoning is that in many cases diagnosis is not obvious from the circumstances. A partially asphyxiated person may be brought to the hospital and either recover or die without any one being aware of the true nature of the illness. Undiagnosed and unsuspected cases of carbon monoxide poisoning occasionally are discovered during the routine autopsy in the medical examiner's office. If the body is that of a person who has been found dead, the characteristic pink or rose colored postmortem lividity and the cherry red color of the organs and blood immediately make the diagnosis apparent to an experienced observer. In an undiagnosed case in which survival has been long enough for the carbon monoxide to disappear from the body, the postmortem diagnosis is more difficult but is suggested by the finding of a bilateral symmetrical softening of the globus pallidus, which occurs in almost every case of acute asphyxiation in which survival in coma has lasted for more than twenty-four hours. This lesion is the most constant finding in delayed deaths from carbon monoxide poisoning; other lesions occur but with much less frequency.

To illustrate the unusual circumstances under which cases of carbon monoxide poisoning occur and how cases may be brought to the hospital for treatment without any suspicion as to the actual nature of the illness, I will relate the following story:

About six months ago, in Manhattan, four persons in a rooming house sat down to a dinner consisting of pork chops, spaghetti, string beans and other victuals. They all ate rather heartily. Immediately after dinner, one person who partook of all the food went outdoors for a walk. He did not become ill. Shortly after his departure the other three persons who had also finished their dinner became ill. They began to vomit and had diarrhea. One person went to the lavatory, where he collapsed and died. The other two ill persons were removed to a hospital in an ambulance. Now it seems logical to conclude, when several persons become ill with digestive symptoms immediately after partaking of the same food, that the food is responsible for the illness. A diagnosis of food poisoning was therefore made in this case and a police detective arrested the butcher who had sold the pork chops and accused him of selling tainted meat. The body of the man who was found dead in the lavatory was sent to the morgue for autopsy as a case of food poisoning. The autopsy, however, definitely revealed that death had been caused by carbon monoxide poisoning. The lividity and the organs and blood were pink because of the presence of carboxyhemoglobin. A chemical examination revealed that 70 per cent of the hemoglobin was saturated with

carbon monoxide. As soon as the cause of death was apparent, the hospital to which the other two victims were taken was notified. The patients were recovering from what had been diagnosed as food poisoning. Carbon monoxide poisoning had not been suspected. Blood had not been taken for chemical examination. The carbon monoxide in this case escaped from the defective flue of a coal furnace in the basement. The diagnosis of nonfatal carbon monoxide poisoning is not easy in the absence of a history of exposure to the gas. With large concentrations of carboxyhemoglobin the skin may show a pinkish flush, but this is not always apparent in the living patient as it is in the suffragations of the dead body. Carbon monoxide poisoning should be suspected in obscure cases of coma attended by marked spasticity of the extremities and the presence of hyperactive and abnormal deep reflexes, clonus and signs suggesting bilateral involvement of the pyramidal tracts.

To establish the diagnosis in a nonfatal case it is necessary to remove a sample of blood for qualitative and quantitative chemical examination for the presence of carboxyhemoglobin. The blood should be taken just as soon as the possibility of carbon monoxide poisoning is considered. A simple qualitative test may be carried out on a few drops of blood by diluting and then adding a few drops of 10 per cent sodium hydroxide solution to the dilute solution. A light pink solution will result and persist after the addition of the alkali. Normal blood in the same dilution will turn a greenish brown on the addition of the alkali. The qualitative tests as well as the spectroscopic tests for carboxyhemoglobin will give positive results only if the concentration of carboxyhemoglobin in the blood is more than 10 per cent.

DR. HARRY GOLD: How much blood do you take?

DR. HELPERN: About 20 cc. is withdrawn and placed in a small, clean, tightly stoppered bottle. Actually the chemist does not require more than 5 cc. for qualitative and quantitative determinations, but enough should be taken to permit duplicate determinations.

DR. GOLD: Do you let the blood clot?

DR. HELPERN: The blood should not be permitted to clot. Usually in fatal cases with high concentration of carboxyhemoglobin no precautions are necessary and the blood will remain fluid. In nonfatal cases, with moderate concentrations of carboxyhemoglobin, the blood may clot in the container unless a small amount of ammonium oxalate or sodium citrate or other anticoagulant is added. It is best to place such blood in a small bottle the inside of which has been moistened with a saturated solution of ammonium oxalate, as in collecting blood used for other chemical analyses. If an anticoagulant is not available, the blood specimen can be shaken in a small, tightly corked bottle. Should the blood clot, qualitative tests can be carried out on the coagulum, which will contain the carboxyhemoglobin. The quantitative tests with clotted blood are more difficult to carry out.

The important thing to remember in a nonfatal case is to take the blood as soon as possible after the diagnosis has been made, since carbon monoxide is rapidly eliminated from the blood after a person who has been exposed to it has been removed from the environment of the gas and allowed to breathe ordinary fresh air. The elimination of carbon monoxide occurs even more rapidly if respirations are stimulated and oxygen administered. In fresh air, about half the carbon monoxide in the system will be eliminated during the first hour of survival; after twenty-four hours, all the carbon monoxide will have disappeared. Thus in such a case

it may be difficult from the medicolegal standpoint to prove that carbon monoxide poisoning actually took place unless a sample of blood for analysis was removed from the patient immediately after exposure to the gas.

In acute carbon monoxide asphyxiation, many persons who are found unconscious survive for twenty-four hours and even longer periods. They may regain consciousness only to lose it again or they may remain comatose until they die. A hypostatic bronchopneumonia may set in. At necropsy, patients surviving for more than twenty-four hours after an acute asphyxiation which has rendered them unconscious manifest a characteristic lesion, which is the most constant finding in delayed deaths from acute carbon monoxide poisoning regardless of the source of the gas. This lesion consists of a bilateral symmetrical anemic softening or necrosis of the globus pallidus, which is readily seen in the brain removed in such a case, which I have brought here today.

Much has been written about so-called chronic carbon monoxide poisoning resulting from the repeated inhalation of small amounts of carbon monoxide never sufficient to produce the clearcut picture of an acute asphyxiation. The variety of ill effects which have been attributed to the repeated inhalation of small amounts of carbon monoxide over a protracted period of time are difficult to evaluate. Carbon monoxide is not a cumulative poison in the sense of being stored in the body. It is rapidly eliminated and its deleterious action is not dependent on any specific action of the gas other than its ability to combine with and appropriate hemoglobin at the expense of its oxygen carrying capacity. Acute asphyxiation occurs because the hemoglobin in union with carbon monoxide cannot carry oxygen to the tissues. A critical analysis of those cases in which it is claimed that a specific organic lesion has resulted from exposure to small nonasphyxiating amounts of carbon monoxide, that is, amounts insufficient to have produced unconsciousness, will not reveal any instance in which some other explanation for the lesion is not just as reasonable or more likely. Too often the medical expert entertains the attractive possibility for such causal relationship, reasoning from the fact that bona fide acute carbon monoxide asphyxiation may be followed by various sequelae resulting from organic lesions which had their inception at the time the acute asphyxiation occurred. Too often, however, this same medical expert when he arrives in a court of law will testify not to the possibility of a causal relationship between the disability in question and exposure to small amounts of carbon monoxide in the past but to the reasonable certainty that such is the case. Why a causal relationship, which has only been considered possible, or at best which cannot be proved outside the law court, should suddenly acquire certainty in the mind of the expert inside the court room is something which I have never been able to understand. There is no real evidence that exposure to small amounts of carbon monoxide causes permanent damage to any particular organ in the body. The nervous system and cardiac lesions attributed to such exposure have been overestimated. For example, in a recent case the brain of a middle-aged man contained small cysts in both basal ganglia which were perfectly explicable on the basis of a cerebral arteriosclerosis. Because he had once worked in a garage, even though there had never been any history of his having been overcome by carbon monoxide, an attempt was made to relate the cysts in the basal ganglion to exposure to carbon monoxide.

DR. WALTER MODELL: Do the tables include deaths from industrial poisonings?

DR. HELPERN: Yes, all fatal poisonings are included. We do not meet with many fatal industrial poisonings in New York City.

DR. JANET TRAVELL: How long can you keep blood between the time of drawing it and the time that the determination of the carbon monoxide content is made?

DR. HELPERN: If the blood is placed in a tightly corked bottle, it can be kept for quite a while before chemical analysis is carried out. The carboxyhemoglobin does not dissociate in the bottle. Sometimes twenty-four hours or longer may elapse before the toxicologist receives the blood. Blood which cannot immediately be sent for analysis should be kept in the refrigerator.

In a dead body, carboxyhemoglobin persists for a long time and its presence may be detected even in cases of marked decomposition. Carboxyhemoglobin can be detected in embalmed bodies exhumed long after burial.

DR. TRAVELL: Do you take the blood under oil?

DR. HELPERN: It is not necessary to cover it with oil; as a matter of fact, we never do.

DR. CATTELL: The various members of the Department of Pharmacology are prepared to discuss the common forms of poisoning which Dr. Helpern has mentioned, but first perhaps it would be well if any of you have further questions to put to Dr. Helpern to have them now.

DR. GOLD: What is the percentage of carbon monoxide in the blood in most of the fatal cases as you encounter them?

DR. HELPERN: In most of the fatal cases in which the victim is found dead of carbon monoxide poisoning, from 50 to 75 per cent and sometimes more of the hemoglobin is saturated with carbon monoxide. Fatal cases have been observed in which only 30 per cent of the hemoglobin was combined. Differences in the percentage of carbon monoxide in the blood of several persons who were found dead together in the same poisonous atmosphere have been observed. Persons who die after a short period of survival away from the atmosphere of carbon monoxide or who have survived short periods of resuscitation will have lower percentages of carbon monoxide in their blood. Quantitative determination of the carbon monoxide content of the blood should be carried out with the Van Slyke manometric apparatus.

STUDENT: What is the best treatment for a case of carbon monoxide poisoning?

DR. HELPERN: I should prefer to leave that to the pharmacologists, who I believe are prepared to discuss treatment.

TREATMENT OF CARBON MONOXIDE POISONING

DR. CATTELL: I am charged with the question of the treatment of carbon monoxide poisoning, and I might say a few words at this time.

What Dr. Helpern said regarding the rate of elimination of carbon monoxide represents a fundamental observation, which points to the rational treatment in poisoning. He told us that in the course of an hour about half the carbon monoxide which is contained in the blood is eliminated. In general, the rate of elimination represents a logarithmic curve and, if the persons continues to respire, the carbon monoxide is eliminated completely from the body in the course of time.

The experiments of Haldane, made on himself, are the classic ones in this field. He found that when the

concentration of carbon monoxide reached a percentage of 0.07 in air, the oxygen being 20.9 per cent, the hemoglobin was half saturated with carbon monoxide. Thus the affinity of hemoglobin for carbon monoxide was found to be about 300 times that for oxygen, and there is formed a relatively stable combination of hemoglobin and carbon monoxide, which interferes with its function as a carrier of oxygen. I should add that more recent studies indicate a somewhat lesser affinity of hemoglobin for carbon monoxide, i. e. about 210 times that of oxygen. The reaction is subject to the laws of reversible reactions in general, and if the concentration of oxygen is increased there will be a tendency to displace the carbon monoxide, and vice versa. Clearly the first consideration in treatment is to provide an adequate supply of oxygen.

In severe poisoning, these people have a greatly depressed respiration as the result of the asphyxia of the centers, so the first procedure in treatment is to give artificial respiration. The increased respiratory exchange favors absorption of oxygen by the blood and the elimination of carbon monoxide through the lungs. This process is considerably aided if artificial respiration is carried on with a high concentration of oxygen, so 100 per cent oxygen may be administered with the aid of a mask.

In 1920 Henderson and Haggard introduced carbon dioxide as a resuscitative measure and showed its effectiveness in stimulating the respiration and in promoting the exchange of gases with the blood. There are special indications for the use of carbon dioxide in poisoning by carbon monoxide, since the respiratory exchange is likely to be inadequate, owing in part to an abnormally low carbon dioxide content in the body. There are two conditions which tend to give abnormally low carbon dioxide tensions: In the first place, during the early stages of poisoning, when the respiratory center is still active, the asphyxia stimulates respiration and carbon dioxide is lost more rapidly than usual; secondly, oxidative processes are interfered with and thus the amount of carbon dioxide formed is less than normal.

Carbon dioxide is thus indicated for the purpose of stimulating the respiration and promoting the replacement of carboxyhemoglobin with oxyhemoglobin. This, however, is not the only advantage of increasing the carbon dioxide content of the blood, for it also facilitates the release of oxygen from the hemoglobin to the tissues and at the same time favors the separation of carbon monoxide from its combination with hemoglobin.

In the matter of drug therapy I need say very little. I would like, however, to quote from a book that has just appeared by Dr. Cecil K. Drinker on the subject of carbon monoxide poisoning. When we consider the circumstances that we are dealing with, a condition which is essentially an asphyxia arising from the inability of hemoglobin to supply oxygen to the cells of the body, and the fact that apart from the asphyxia there is no deleterious action of carbon monoxide in the tensions obtaining during poisoning, it becomes apparent that we can expect very little from drug therapy.

Dr. Drinker, in introducing the subject, remarks that bystanders feel that the doctor should do something, and the thing done is usually a hypodermic injection of some drug. Then he says:

I have records of the use of strychnine, caffeine, camphorated oil, atropine, digitalis, pituitary extract, adrenin, alpha-Jobeline, methylene blue, and even morphine. The hypodermic injection of any of these drugs in carbon monoxide asphyxia is a forcible indictment of the present teaching of medical students as to

the management of asphyxia; the more so, since often when one drug produces no effect, several more are administered.

It is a fact that practically every possible or impossible drug has been used in carbon monoxide poisoning, and it is doubtful if any of them influences the result.

He then goes on to discuss the objections to the use of these substances, and the only one for which he sees a possible usefulness is caffeine as a respiratory stimulant, but it is clear that he doubts the efficacy of this drug as well. So much for carbon monoxide.

DR. GOLD: Would Dr. Drinker not put the patient into an oxygen tent?

DR. CATTELL: When I referred to drug therapy I had in mind treatment other than by oxygen and carbon dioxide. He favors the procedure now in general use of artificial respiration using, when available, a mixture of 7 per cent carbon dioxide and 93 per cent oxygen administered through a face mask.

STUDENT: Can you base your prognosis on the amount of carbon monoxide you find in the blood immediately after you see the patient?

DR. HELPERN: Yes, I think that is an important point to consider. If a person has inhaled a considerable amount of carbon dioxide and the blood shows a high percentage of saturation with carbon monoxide, the danger of a fatal outcome or of serious sequelae is greater than after the inhalation of smaller amounts of the gas with lower percentage concentration of the gas in the blood.

STUDENT: Are there any residual effects of disease in those cases in which recovery occurs?

DR. HELPERN: In some cases of carbon monoxide poisoning in which there has been a real asphyxiation during which the patient was unconscious, recovery may take place but with distressing residual effects, chiefly referable to the nervous system. Mental deterioration or persistent paralysis may occur. I think Dr. Hausman has probably seen such cases which followed acute carbon monoxide poisoning. However, many patients who recover do so completely without any sequelae.

DR. LOUIS F. HAUSMAN: I might mention one point. The question arises as to whether or not some forms of chronic parkinsonism may follow carbon monoxide poisoning. As stated by some authorities, some of the cases of chronic Parkinson's disease are found in chauffeurs or taxicab drivers who may be exposed to the fumes of an exhaust pipe with carbon monoxide. I should like to ask Dr. Helpern whether he thinks that is a plausible suggestion in those particular cases.

DR. HELPERN: Do more cases of Parkinson's disease occur in chauffeurs or taxi drivers than in those engaged in other occupations? I think that is a question which must first be answered. Unless it can be shown that the chauffeur had suffered a real acute asphyxiation from inhaling carbon monoxide in motor exhaust fumes, I should feel inclined not to attribute his Parkinson's disease to that cause. Considering the number of chauffeurs, taxi drivers and traffic policemen who inhale motor exhaust fumes, there should be many more cases of Parkinson's disease from this source if there was a definite relationship between the disease and exposure to small amounts of carbon monoxide.

DR. HAUSMAN: Except in the few cases we have had here, the one or two in which the blood has been examined, there seems to be an increase in the concentration of the poison in the blood stream.

DR. HELPERN: I do not think that the presence of a small amount of carbon monoxide in the blood in

such a case really indicates any more than that the patient had been exposed to carbon monoxide on that particular day. It does not prove anything as to the presence of carbon monoxide in his blood the day or a week or a year before or at such time in the past when his disease had its inception. Carbon monoxide is not stored in the body like lead or arsenic to be excreted over long periods of time. The fact that small amounts of carbon monoxide are found in a chauffeur's blood today does not imply that a chronic degenerative disease from which he is suffering was caused by exposure to carbon monoxide a long time before.

DR. CATTELL: There are several other substances that we need to consider, so perhaps we shall leave carbon monoxide poisoning and ask Dr. Gold to take up barbiturate poisoning.

BARBITURATE POISONING

DR. GOLD: A few days ago I asked a house officer whether he had seen a case of barbiturate poisoning during his residency. He replied that he had seen one case.

"What barbiturate was it?"

He said he didn't remember but that it was one of them.

"How much did the patient take?"

His answer was: "A bottleful."

"What was the course?"

"She slept a few days and recovered."

It did not seem profitable to pursue the questioning. The patient's chart shed little additional light. I cite this because it is quite typical of the character of the information that is often secured in cases of human poisoning. No wonder at all that the efficacy of a method of therapy is so difficult to evaluate.

The usual situation in the case of barbiturate poisoning which requires vigorous treatment and which offers a chance of success involves an individual in coma, with pupils that are usually contracted—only in the terminal stages does one find a dilated pupil in these cases—rapid, shallow and jerky respiration, cyanosis, usually collapsed veins, cold extremities. The pulse is generally very fast, as high as 150 a minute, and feeble. The blood pressure is low. The reflexes are absent. Sometimes there is a high fever, up to 105 or 106 F., and if there is some moisture in the throat or bronchi the case looks very much like a bronchopneumonia. Sometimes the temperature is subnormal. Depending on the severity of the poisoning, extent of exposure and kind of treatment, the case pursues one of two courses: recovery or death.

The cause of death in clinical barbiturate poisoning is complex. It involves depression of the respiratory center, the heart and the vasomotor center. All of these are depressed by the drug directly, but each also suffers indirectly from the poor function of the others. A vicious circle is therefore set up with inadequate breathing and circulation. Failure of the respiration is generally the immediate cause of a fatal issue. Primary failure of the heart is rarely, if ever, a cause of death in these cases, because the drug paralyzes the nerve centers long before so much damage is done to the heart. These facts have a bearing on our choice of procedures in treatment.

The first thing to do is to insure the fact that the patient has clear air passages, to draw the lower jaw forward and pull out the tongue if possible. Not infrequently that simple expedient will be sufficient to reverse the course of a case which may at first seem

almost hopeless. The relaxed tongue against the soft palate or pharynx may seriously impair the movement of air into the lungs. This is one of the chief causes of disaster when the barbiturates are used as general anesthetics.

Then one treats the patient by the usual technics employed in the control of secondary shock. He is wrapped in warm blankets, and hot water bottles or electric pads are applied to the extremities. Intravenous infusions of 5 per cent dextrose and physiologic salt solutions are given continuously, about 2 liters a day.

Several physiologic antidotes have been used with varying success, namely strychnine, metrazol, caffeine, ephedrine and picrotoxin. I shall speak only about the one which is now occupying the center of the stage, namely picrotoxin. Koppányi and his associates appear to have been the first to put this drug to use effectively in cases of barbiturate poisoning. It is a strong stimulant of the central nervous system, the cortical centers and the medullary centers. In large doses it causes clonic convulsions similar to those of camphor. It is soluble in water to the extent of about 0.5 per cent. One of the available preparations is a vial containing 20 cc. of a 0.3 per cent solution or 3 mg. per cubic centimeter. The usual technic is to give from 3 to 10 mg. by intravenous injection (or intramuscular injection) and repeat the dose as necessary at intervals of from one to ten minutes in the case of the intravenous route. The full effects of an intravenous injection of this drug often take about five minutes to develop. The object is to keep on repeating the dose until effects appear. What effects is one to expect? They are signs of stimulation, hyperactivity of the skeletal muscles, some myoclonic movements; the finger may flick or the hand may turn over spontaneously; the depth or rate of respiration may increase. When these signs of stimulation appear, an endeavor is made to retain them by repeated injections, and the intervals as well as the size of the repeated doses will be a matter of judgment. Do not give doses large enough or frequently enough to provoke convulsions. Do not try directly to restore consciousness. The drug will not restore consciousness rapidly in deeply narcotized individuals even in doses which cause violent convulsions. The patient regains consciousness only after many hours of treatment. The immediate object is to maintain adequate respiratory and circulatory function by the stimulant. Total doses of more than 2 Gm. of picrotoxin have been given in the long course of poisoning by the barbiturates.

If an overdose of picrotoxin is given, the resulting convulsions may be suppressed by a dose of a barbiturate.

Not all cases of barbiturate poisoning need to be treated with picrotoxin. Recovery occurs in the milder cases without it. Even in very severe cases in which the dose of barbiturate was very large, for example amytal sodium 100 grains and barbital 300 grains, survival has occurred after narcosis for three days or longer, with supportive treatment alone. The general mortality among patients who reach the hospital with barbiturate poisoning is less than 25 per cent. Up to the present time picrotoxin does not seem to have changed these figures. Clinical cases of poisoning are often complicated by the existence of disease or prolonged exposure which may lead to bronchopneumonia. However, the reported cases are not sufficiently numerous for valid statistical examination. There is sufficiently strong pharmacologic proof that the drug

is effective to justify its use for patients profoundly depressed by barbiturate poisoning.

I have not mentioned the matter of washing the stomach in barbiturate poisoning. This is a procedure one thinks of at once in all cases of poisoning by the oral route. If the depression is profound and reflexes are suppressed, I should refrain from washing the stomach. The danger of aspiration pneumonia under these conditions is greater than the good this procedure can do. In cases in which the patient is conscious or only in a state of stupor, gastric lavage may be done with water or 1:5,000 solution of potassium permanganate. It is well to bear in mind that not all the barbiturates are decomposed by potassium permanganate; in fact, those most commonly involved in cases of poisoning are not, namely barbitol, phenobarbital and amytal.

CORROSIVE POISONING

DR. CATTELL: Dr. Travell, I wonder if we could have a few minutes' discussion of poisoning by phenol and other corrosives.

DR. TRAVELL: I will abbreviate what I was going to say. My topic will be the treatment of poisoning by phenol and its allied compounds, the cresols. The cresols, or alkyl phenols, are the chief constituents of lysol. They are less toxic than phenol itself, but the toxic actions and fate in the body are qualitatively the same.

First as to the antidotal value of ethyl alcohol in poisoning by phenols: A 10 per cent solution of alcohol is now recommended for gastric lavage by Sollmann and some textbooks on toxicology. This recommendation seems to be based on the fact that alcohol is a better solvent for phenol than are the tissue fluids; thus a dilute solution of phenol in alcohol will produce less blanching and tingling of the fingers, or less whitening of the mucous membrane, than the same concentration of phenol in water. This is seen both experimentally in animals and in human cases of poisoning in which alcohol has been taken with phenol. However, the general toxicity of phenol is increased when alcohol and phenol are given together orally. Macht has shown that if the two drugs are given simultaneously by mouth the onset of symptoms is accelerated and death may be hastened, and Simon has also shown that the concentration of free phenol in the blood from ten to thirty minutes after its administration is appreciably higher when it is given with alcohol than when it is given with water. These experiments indicate that alcohol increases the rate of absorption of phenol from the stomach. Although it is sometimes stated that alcohol is directly antagonistic to phenol after absorption, there is no satisfactory evidence that there is any such physiologic antagonism.

On the basis of the available evidence I would recommend that alcohol should not be used as an antidote for phenol taken by mouth, even in dilute solution for gastric lavage. This is all the more true since we have a better solvent for phenol, namely glycerin, which is also usually available for lavage. Glycerin as well as alcohol reduces the local irritant action of phenol but does not increase its toxicity when given at the same time by mouth. On the contrary, Macht's experiments suggest that phenols may be less toxic when given in a 10 per cent solution of glycerin.

Oils are good solvents for phenol and have also been found experimentally to reduce the minimal fatal dose of phenol, especially olive oil and cottonseed oil, and

some other fixed oils. Castor oil is said to be one of the best. This does not apply to mineral oil, for the solubility of phenol in this substance is quite small, about 1 in 50 parts, and mineral oil affords no protection against a fatal dose of phenol.

In summary, the following procedures might be recommended for the treatment of poisoning by the phenols taken by mouth: As first aid measures, one should give a quantity of olive oil, cod liver oil, cottonseed oil, castor oil or whatever vegetable oil is available, and also administer egg white, because egg albumin precipitates phenol and may delay its absorption. Secondly, thorough gastric lavage with a 10 per cent solution of glycerin should be carried out and, if this is not available, lavage with water. The stomach should be lavaged even as late as an hour or two after the drug has been taken, since absorption is probably not complete within this period of time.

Unlike poisoning by the corrosive acids and caustic alkalis, it appears to be quite safe to pass a stomach tube, for I have not found any reports of perforation of the stomach in phenol poisoning. After lavage, a large dose of castor oil should be introduced into the stomach through the stomach tube. Acute symptoms of poisoning, such as circulatory shock and respiratory depression, should be treated as occasion demands. Of course, eschars on the skin should be washed with a 25 per cent solution of either alcohol or glycerin.

Just a word about the treatment of poisoning by concentrated acids and alkalis. In these instances a stomach tube should not be introduced. For chemical neutralization, weak acids or alkalis should be administered by mouth, such as vinegar, lemon juice and tartaric acid for poisoning by alkalis, and milk of magnesia and lime water as antidotes for poisoning by acids. The alkaline carbonates, which liberate carbon dioxide, should not be employed as antidotes.

POISONING WITH MERCURY AND LEAD

DR. CATTELL: There are several other important groups which we unfortunately have not yet covered, but I wonder if we could have a few minutes from Dr. Modell to deal with the metals.

DR. MODELL: Poisoning with mercury bichloride is dangerous and difficult to treat because of the rapidity with which it produces local damage and the promptness with which it is absorbed from the gastrointestinal tract and from other mucous surfaces. Irreparable damage to the kidneys and other organs follows quickly. Ten minutes after the oral administration of mercury to dogs, lesions in the kidneys have been demonstrated. In a large series of cases it was shown that the mortality rate mounted sharply when emesis or lavage was delayed for much more than fifteen minutes after the ingestion of the poison.

Mercury bichloride poisoning, therefore, should be considered an emergency and treated with as much dispatch as one would a severed artery or a case of suffocation; minutes may be of vital importance. The important thing is to empty the stomach promptly. The most readily available means should be used to induce emesis. The stomach should be washed, using water alone if an antidote is not handy.

A number of chemicals have been used with the wash water to precipitate the mercury and to delay its absorption, but there is no satisfactory proof that any of them has had an appreciable effect on the high mortality rate in mercury bichloride poisoning. Recently,

however, sodium formaldehyde sulfoxalate was introduced by Rosenthal as a chemical antidote. It is by far the most promising agent thus far suggested. It reduces the mercury bichloride to metallic mercury. Its action can be accelerated by the addition to the solution of a mild alkali such as sodium bicarbonate. Sulfoxalate can protect animals against doses of mercury bichloride which would otherwise be fatal, but its ability to save animals is not great if as long as fifteen minutes to half an hour elapses before it is given and if the doses of mercury bichloride have been very large.

A 10 per cent solution of sulfoxalate with 5 per cent of sodium bicarbonate may be used for washing the stomach. The solution should be freshly made, but time need not be wasted in making such a solution accurately since sulfoxalate is not very toxic. After washing, about 200 cc. of such a mixture may be left in the stomach. An intravenous injection of from 10 to 20 Gm. of sulfoxalate in a 10 per cent solution may also be given. The injection should be made slowly. A variety of programs for after-care have been suggested. The treatment will depend on the symptoms which develop.

I would like to say a few words about lead poisoning, because in chronic lead poisoning the treatment differs radically from that used in most other types of poisoning. Generally one tries to get rid of the poison as rapidly as possible, but in the treatment of chronic lead poisoning the elimination of lead is regulated so that it is slow, and in acute episodes an attempt is made to stop the elimination of lead entirely.

Lead is stored in the bones and while there it does essentially no harm except, possibly, for its action on the teeth. When lead is mobilized from the bones and circulates through the body in an appreciable concentration it may cause disturbances by attacking the kidneys, liver and central nervous system, or it may precipitate an attack of colic.

The lead stream parallels the calcium stream, and any measure which makes for the deposition of calcium in the bones also makes for the deposition of lead there, and, conversely, the mobilization of calcium from the bones leads to the liberation of the lead which is stored there.

The principles of treatment follow this relationship. In acute lead episodes a high calcium diet is used to bring about a deposition of lead in the skeleton and to allay symptoms. In the treatment of lead colic, the intravenous injection of 15 cc. of a 10 per cent solution of calcium chloride is often followed by a dramatic disappearance of the pain.

After the acute symptoms have subsided, the question arises whether the patient should be delead. The considerations which favor deleading are that lead in the bones is a potential source of acute exacerbations; that these episodes may be brought on by acute infections, metabolic disturbances, disturbances in acid-base equilibrium, low calcium diet and drugs. Furthermore, after such episodes the lead is not necessarily eliminated but may be redeposited in the bones, and the cycle may be perpetuated. Deleading must be slow and carefully controlled to avoid acute toxic effects. A low calcium diet and an acidifying agent such as phosphoric acid or ammonium chloride are the essentials of the usual regimen.

DR. CATTELL: I regret that we cannot have all those questions which we would like to ask, but the hour for adjournment has already passed.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
HOWARD A. CARTER, Secretary.

HOGAN BREVATHERM PREMIER MODEL ACCEPTABLE

Manufacturer: McIntosh Electrical Corporation, 223-233 North California Avenue, Chicago.

The Hogan Brevatherm Premier Model is a mobile short wave diathermy unit intended for use in medical and minor surgical diathermy. The unit investigated was designated by number 8685, while other serial numbers represent the same machine in different finishes and styles but with the same hookup and electrical characteristics. It is available with a sub-cabinet. Standard accessories include plate, cuff and pad electrodes and rubber bandages. Optional accessories consist of air-spaced plates and localizing disks, treatment arms, induction cable, official applicators and electrosurgical instruments.

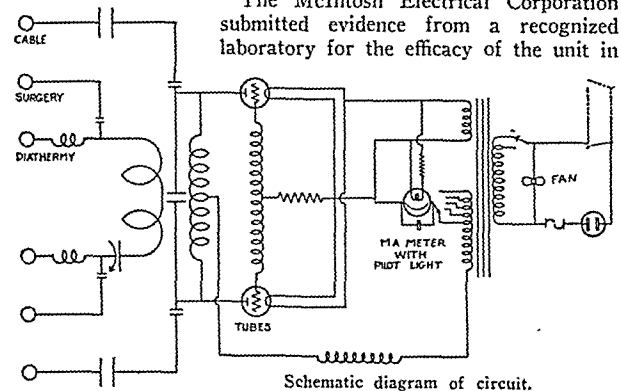

Hogan Brevatherm Premier Model.

Two vacuum tubes in a tuned-plate, tuned-grid, push-pull oscillator circuit generate high frequency energy at a wavelength of about 12 meters. The patient circuit is inductively and capacitively coupled to the oscillator circuit. There is fan-cooling ventilation in the upper part. The shipping weight for upper and lower sections is 228 pounds. The overall size is 22½ inches wide, 42½ inches high and 16½ inches deep.

The output was found to be 315 watts when the lamp load method was used connected to a 110 volt line. The temperature rise in the outside windings of the transformer after two hours of operation at a full input was within the limits of safety.

The McIntosh Electrical Corporation submitted evidence from a recognized laboratory for the efficacy of the unit in

producing heat deep within human tissues. Temperatures were taken initially and after twenty minutes application. Current was applied in accordance with the patient's skin tolerance for heat. In the cuff technic the spacings between the cuffs and the skin were as follows: three thicknesses of flannel, four of toweling and from three-eighths to five-eighths inch thickness of felt.

Average Temperatures (F.) for Six Observations

Technic	Deep Muscle		Oral	
	Initial	Final	Initial	Final
Air-spaced electrode.....	99.3	105.4	98.5	*
Cuff	97.7	106.2	97.9	*
Cable	98.7	105.8	98.4	*

* Not observed.

The unit was tried out clinically by a qualified investigator, who reported it to be as effective and satisfactory as any other unit which he had tested. As no evidence was submitted for fever therapy, he did not test the machine with this technic. He advised that the Hogan Brevatherm Premier Model be accepted for air-spaced, cable and cuff technics only.

In view of the foregoing report, the Council on Physical Therapy voted to include the Hogan Brevatherm Premier Model in its list of accepted devices.

SATURDAY, AUGUST 5, 1939

FEDERAL COURT HOLDS GOVERNMENT INDICTMENT AGAINST AMERICAN MEDICAL ASSOCIATION INVALID

Elsewhere in this issue of THE JOURNAL appears the full text of the opinion of Justice James M. Proctor in the District Court of the United States for the District of Columbia on the demurrer to the indictment against the American Medical Association. Associated with the publication of this opinion are transcripts of a number of editorials which have appeared in newspapers in the brief period that has elapsed since the decision was first announced. Also there appears a press release issued by the Department of Justice for morning papers of July 27, indicating that further action is contemplated by the Department of Justice in relation to this case.

After indicating the nature of the indictment and the five forms of conspiracy that were charged, Justice Proctor listed the chief contentions of the demurrer. It is his opinion that medical practice is not a trade within the meaning of section 3 of the Sherman act. Particularly interesting in Justice Proctor's opinion is his analysis of the indictment. Thus he said:

The defendants have raised objections to the sufficiency of the indictment as a pleading. These go mainly to the claim that many of the allegations dealing with essential and material features of the charge are vague, indefinite and uncertain. The objections are far too numerous to deal with separately. There is merit to many of them. The indictment is afflicted with vague and uncertain statements. In some instances material facts are altogether lacking.

Moreover, he said in relation to that part of the indictment which contained the charges against those indicted:

The inducement, as well as the charging part, setting forth the plan and purpose and acts done to effectuate the conspiracy, abound in uncertain statements. Inference, opinion and conjecture are also freely indulged. This is especially so in the inducement, much of which seems unnecessary to a statement of the charge. It is questionable whether some of it would be deemed relevant and competent in proof of the offense. Every indictment should be confined to a clear and dispassionate statement of essential fact. Thus an accused can better know the exact offense with which he is charged and will not be confused in making his defense. Ordinarily improper matter in the

indictment unnecessary to support the charges will not vitiate the indictment. It will be treated as surplusage and disregarded. But I doubt if such treatment would suffice to relieve these defendants of the prejudice likely to arise by an indictment which smacks so much of a highly colored, argumentative discourse against them. It must be remembered that when a case is finally submitted to a jury for their secret deliberations the indictment goes with them.

In its press release, the Department of Justice indicates that it will seek a reversal of the decision handed down by Mr. Justice Proctor. It makes the statement that the release is issued not for the purpose of commenting on the opinion but for the reason that it is important to inform physicians generally that, until the Supreme Court has acted, the government policy toward boycotts in the medical profession is unchanged. The Department of Justice says further that it will use every effort to get a final decision from the Supreme Court at the earliest possible moment and that it may consider the possibility of calling another grand jury to consider another indictment in a different technical form. Finally the Department of Justice states that announcement of the exact steps which will be taken by the government will be made within the next ten days.

In response to this pronouncement of the Department of Justice, Mr. Seth W. Richardson, one of the attorneys representing the American Medical Association, gave the following interview:

The warning issued by the Anti-Trust Division [of the Justice Department] to the medical profession generally, following the filing of the decision of the District Court on demurrer, was both impertinent and unnecessary.

It was impertinent because, as the division should know, the government has no jurisdiction whatever over the medical profession, save in the District of Columbia, and medical men elsewhere need pay no attention to the threats of the Anti-Trust Division.

The "warning" was unnecessary because the members of the medical profession did not, do not and will not violate any of the antitrust or other statutes in the pursuit of their calling.

Finally, with reference to the statement of the division that the present decision is not a controlling precedent and that new grand jury proceedings may follow, it is sufficient to reply that until the present ruling is reversed counsel for the defendants believe that it stands as an effective bar to any similar abortive attempts on the part of the division to make further legal "experiments" upon the doctors in the District of Columbia.

The conclusion seems inescapable that the Department of Justice has embarked on a course of prosecution if not persecution of the medical profession in this country with a view to forcing its contentions as to what should be the nature of medical practice in the United States. Failing to obtain a consent decree, it proceeded to secure an indictment. Attorneys for the American Medical Association, obeying the mandate from its Board of Trustees, sought to obtain a quashing of the indictment by the filing of a demurrer. Now Justice Proctor has declared in no uncertain terms that the demurrer is sustained and has indicated that much of the language of the indictment is "highly colored, argumentative discourse." Not satisfied with

this decision, the Department of Justice proposes to continue to seek to undermine the confidence of the people in the medical profession. The question may well be asked as to whether or not this is justice or persecution. The members of the House of Delegates of the American Medical Association have authorized the Board of Trustees and the officers to utilize to the utmost the resources of the Association in combating this attack by the Department of Justice. The opinion of Justice Proctor lends encouragement and is an inspiration to continuous effort in behalf of a free profession. The medical profession of this country will not be coerced, threatened, abused or otherwise maltreated, and it will fight to the finish when its high traditions demand a righteous resistance.

PSYCHOSOMATIC MEDICINE

In January appeared the first issue of a new periodical to be published quarterly under the title *Psychosomatic Medicine*.¹ As new concepts develop in the activities of our day, new words are coined to indicate their character. For centuries physicians have known that it is impossible to treat the body as if separate from the mind or the mind as if distinct from the body. In more recent years renewed emphasis has been placed on this point of view. The special attention paid to the constitution of the human being in relation to his growth and development and diseases has inspired the creation of special departments in medical schools devoted to the study of constitution and heredity. The dynamic psychology of Sigmund Freud placed new emphasis on the psychologic bases of many physical disturbances. The ultimate step would seem to be the present attempt to integrate these interests in the field of medical science by a psychosomatic approach.

We are not concerned in this new phase of medicine with the metaphysical approach to illness. We are concerned rather with the attempt to study cases of diseases by the scientific method with a view to determining not only the physical disorders that exist and the physical basis for such disorders but also the extent to which the mind of man is implicated in the cause of illness, modifies disease processes and controls recovery. For example, it is already well recognized that the condition called asthma may involve, in the vast majority of instances, the sensitization of the body to protein substances, such as the pollen in plants, the proteins of foods or the dandruff from domestic animals. But it is also recognized that the symptoms and their onset may be closely related to the extent to which the specific physiologic factors act in the presence of specific physical or physiologic states to produce a disturbance of function. For the condition called essential hyperten-

sion, which involves a persistent unexplained rise in the blood pressure, there are innumerable theories as to the mechanism of its production. The evidence established by Goldblatt related to the circulation of the kidney is significant. Important also, however, is the well established evidence of the effect of the emotions on the blood pressure in an individual, in whom both physical and mental factors play a part in producing a rise. This complex is surely a suitable subject for the study which such a patient may have, either by a single physician who is aware of both the physical and the mental approach or by a group of physicians who make individual observations and correlate the results. Thus psychosomatic medicine is not a revolutionary departure from well established laboratory medicine or from psychology. It brings instead to the study of disease an attack in which it is specifically recognized that every human being is a whole individual and not a loose combination of physical and psychic factors. The new method also takes into account the necessary study of the anatomy, physiology and pathology of the nervous system in relation to the mechanisms behind the development of symptoms. Psychosomatic medicine, indeed, attempts to bring about a complete combination of art and science in the practice of medicine, through a systematic technic.

The first two issues of the new publication *Psychosomatic Medicine* emphasizes this technic as applied to hypertension and to asthma in individual cases. There are also reports of basic studies on animals. A distinguished list of editors responsible for various departments in the field gives promise of selection of a high quality of material from the new reports which may soon become available in this field.

THE SUPPORT OF A FAILING CIRCULATION

Many a surgeon has watched a patient sinking into traumatic shock and realized that all that he could do by infusion of saline solution, transfusion of blood, use of epinephrine, lifting the foot of the bed and other measures still left the failing circulation inadequately supported. Many a physician has observed a patient exhausted by illness sinking in essentially the same manner. Some element in the mechanics of the circulation has remained inadequately defined and therefore beyond therapeutic control.

Forty years ago the progressive weakening of the pulse and of the sounds of the heart in these conditions was interpreted as a progressive failure of the force of the heart. Then, as the conception of the nervous control of arterial pressure was developed by physiologists, as the sphygmomanometer was introduced into clinical medicine and as the failure of the circulation was found to be expressed always in a progressive fall of arterial pressure, the underlying cause was inferred

1. *Psychosomatic Medicine* 1:1-200 (Jan.), 201-332 (April) 1939, published quarterly with the sponsorship of the Committee on Neurotic Behavior, Division of National Research Council, 2101 Constitution Avenue, Washington, D. C., annual subscription \$5.

to lie in failure of the vasomotor nervous system.¹ Yet, as Porter² and Henderson³ early pointed out, this explanation left much still to be explained. Henderson even ventured to assert that the failure, both of the heart action and of arterial pressure, is secondary to failure of what he called the "venopressor mechanism." Gradually it has come to be almost universally accepted by physiologists, who based their decision on the accumulated evidence, that the underlying cause of a failing circulation is a progressively diminishing venous return.⁴ The heart can pump into the arterial system only what it receives from the venous system; no degree of vasomotor activity can maintain arterial pressure if the output of the heart falls too low. Evidently the fundamental condition is the stagnation of blood in the body tissues. But why does such stagnation occur after severe physical injury and suffering, after major surgical operations and as a terminal event in illness?

Turning this question backward, Henderson and his collaborators⁵ posed the question: May it be that the tonus of the musculature of the body, both skeletal and visceral, produces and maintains throughout the body a gentle pressure that normally plays a major part in sending the blood from the tissue capillaries into the veins and on back to the heart? And may it not be that in states of physical depression this tonic intratissue pressure is also depressed and with it the venous return? For this conception evidence is now rapidly accumulating, both experimental and clinical. Schubert⁶ has found that some such explanation is probable in those cases in which a shocklike condition appears under spinal anesthesia. Now Ornstein, Licht and Herman⁷ report a method of raising venous pressure to be used in surgical and traumatic shock, particularly applicable to failure of the circulation under spinal anesthesia.

The technic involves the application of wide electrodes of toweling soaked in physiologic solution of sodium chloride round the lower part of the abdomen and the lower lumbar and gluteus muscles with a belt of block tin outside the toweling. Each leg is encased in similar electrodes. These electrodes are then connected to an inductorium and a gentle, quite easily bearable faradic current is turned on. The result in normal persons is always a distinct increase of venous pressure. Although the cases of serious circulatory depression in which the treatment has been applied are as yet few, the effects are so definite as to justify the hope that

this therapy may at least solve the problem of failure of the circulation under spinal anesthesia.

Evidence from other sources indicates that the most effective means to combat failure of respiration under spinal anesthesia is intratracheal insufflation.

Current Comment

APPLICATION OF AN ENZYMIC REACTION IN CHEMICAL METHODS FOR THE DETERMINATION OF VITAMIN B₁

The development of chemical methods for the determination of vitamins is of practical importance since such methods make assays easily possible. The assay by chemical means of vitamin B₁ is complicated; this factor exists in many biologic materials both as thiamin and as cocarboxylase, the pyrophosphate of thiamin. Indeed it has been found that thiamin pyrophosphate is the predominant form of vitamin B₁ in many yeasts and animal tissues. When applied directly to such materials, chemical methods depending on the reaction between thiamin and diazotized *p*-aminoacetophenone or on the formation of thiochrome from thiamin yield values decidedly lower than those obtained by biologic assay. The method involving the use of *p*-aminoacetophenone is specific for thiamin and does not permit the determination of the vitamin in the phosphorylated form. Similarly it has been reported that the thiochrome formed from thiamin pyrophosphate, unlike that from unesterified thiamin, cannot be extracted by butyl alcohol and hence cannot be estimated. In recent modifications of chemical procedures for the estimation of vitamin B₁ in materials containing thiamin pyrophosphate the cocarboxylase is first converted enzymatically to thiamin, in which form it can be readily determined. Thus in a method recently described by Melnick and Field¹ advantage is taken of the fact that an aqueous extraction of yeast powder at room temperature yields solutions which will completely hydrolyze added phosphorylated thiamin. Incubation of active yeast powder with vitamin B₁ concentrates, such as rice polishings and wheat germ, converts all the phosphorylated vitamin present into unesterified thiamin, after which it may be determined accurately by measurement of the color developed on addition of diazotized *p*-aminoacetophenone. The concentration of the vitamin in the phosphorylated form can be estimated by difference between the thiamin values obtained before and after this hydrolysis. Likewise Hennessy and Cerecedo² found that the vitamin B₁ content of materials containing cocarboxylase could be determined by a modified thiochrome method if the cocarboxylase present was converted to thiamin by an enzyme preparation prior to the assay. The results obtained by the thiochrome method after this treatment were generally found to be in good agreement with the values obtained by bio-assay.

ORGANIZATION SECTION

OPINION OF JUSTICE JAMES M. PROCTOR IN THE UNITED STATES DISTRICT COURT FOR THE DISTRICT OF COLUMBIA, JULY 26, 1939, ON THE DEMURRER TO THE INDICTMENT AGAINST THE AMERICAN MEDICAL ASSOCIATION

The indictment charges a conspiracy to restrain trade in the District of Columbia in violation of section 3 of the Sherman Anti-Trust Act. The defendants are American Medical Association, a national organization of physicians; two of its subordinate bodies, the Medical Society of the District of Columbia and Harris County Medical Society of Houston, Texas, also the Washington Academy of Surgery, not fully identified, and twenty-one individual doctors all members of the national body, some officers thereof, other members and officers of the Medical Society of the District of Columbia. All defendants have demurred to the indictment. It is very long, and only abbreviated references will be made to such parts as are deemed necessary to this decision.

Group Health Association, Inc. (hereinafter called association), is alleged to be an association of government employees, engaged "in the business of arranging for the provision of medical care and hospitalization to its members and their dependents on a risk-sharing prepayment basis." Medical care is provided by a staff of salaried practitioners engaged in group practice under a medical director. A clinic is maintained, and limited hospital expenses are defrayed for the members and their dependents.

The defendants are alleged to have conspired (1) to restrain the association in its business of arranging for the provision of medical care and hospitalization to its members and their dependents, (2) to restrain such members in obtaining, by cooperative efforts, adequate medical care for themselves and their dependents from doctors engaged in group medical practice, (3) to restrain doctors serving on the medical staff of the association in pursuit of their callings, (4) to restrain other doctors in the District of Columbia, including some of the individual defendants, in pursuit of their callings and (5) to restrain Washington hospitals in the operation of their businesses.

The demurrers raise basic objections to the indictment. Of first importance is the contention that none of the alleged restraints has reference to a trade; that section 3 comprehends only those occupations in commercial life carried on in the marts of trade activity; therefore, that the medical profession and the business of the association and hospitals do not constitute "trade" within the purview of the statute. Against this contention, the government's position is that all who are occupied in any activity whereby they supply money's worth for full money payment are engaged in trade; that section 3 does cover all such activities; therefore that the practice of medicine and the businesses of the association and hospitals do fall within the scope of the statute.

Is medical practice a trade within the meaning of section 3 of the Sherman Act? In my opinion it is not. I think the matter is settled by the Supreme Court in the case of *Atlantic Cleaners & Dyers v. United States*, 286 U. S. 427. That case squarely presented the question whether "trade" is used in a narrow sense, as importing "only traffic in the buying, selling or exchanging of commodities," or in a broader sense. It fairly called for a definition of the word. This the court undertook to give. In so doing, it declared that the word "trade" was used in section 3 of the Sherman Act in the general sense attributed to it by Justice Story in the case of the *Schooner Nymph*, 1 Summ. 516; 18 Fed. Cases 506, No. 10,388. The court, intending to give a full and broad meaning, adopted for its own definition for "trade" the language of Justice Story in that early case, quoting therefrom as follows:

"The argument for the claimant insists that 'trade' is here used in its most restrictive sense and as equivalent to traffic in goods, or buying and selling in commerce or exchange. But I am clearly of opinion that such is not the true sense of the word, as used in the thirty-second section. In the first place, the word 'trade' is often and, indeed, generally used in a broader sense as equivalent to occupation, employment or business, whether manual or mercantile. Wherever any occupation, employment or business is carried on for the purpose of profit, or gain, or a livelihood, not in the liberal arts or in the learned professions, it is constantly called a trade. Thus, we

constantly speak of the art, mystery or trade of a housewright, a shipwright, a tailor, a blacksmith and a shoemaker, though some of these may be and sometimes are, carried on without buying or selling goods."

PROFESSION EXPRESSLY EXCEPTED

Thus we have this recent controlling decision defining the word trade and expressly excepting the learned professions of which admittedly the practice of medicine is one. The decision is in harmony with others rendered before and after the *Cleaners and Dyers* case. See *Fed. Trade Comm. v. Raladam*, 283 U. S. 643; *Graves v. Minnesota*, 272 U. S. 400 and *Semler v. Board*, 294 U. S. 608. The restraints alleged against the doctors in specifications three and four of the charge are clearly not within the purview of the statute. I cannot accept the refinements of thought whereby it is argued for the government that the Court in quoting Justice Story was not defining "trade" but merely illustrating the narrow and broad concepts of the word. Nor does the decision lend any support to the idea that by enacting section 3 Congress intended to exercise all its plenary power over the District of Columbia to prohibit restraints against all business activities of the citizen. The Court has simply said that Congress meant to deal effectively with the evils resulting from contracts, combinations and conspiracies in restraint of trade—not all restraints upon every business pursuit, but only those affecting trade.

Doubtless, in the fulness of its power over the District, Congress could have prohibited restraints upon all occupations of the citizen. But there is nothing in the history of the legislation to suggest the need for such a broad reach of power and clearly it was not intended.

The government has cited many English and American cases dealing with restrictive covenants ancillary to agreements by doctors concerning the sale or conduct of their practice, in which the courts have applied the common law doctrine as to "contracts in restraint of trade." It is argued that these cases have, in a legal sense, drawn medical practice within the orbit of trade, giving to the word a common law meaning to include the professions. From this, it is further argued that at common law restraints upon the practice of medicine were "restraints of trade" and that Congress in the Sherman Act used the term in such a sense. But those cases are beside the point.

They do not involve any question as to whether medicine is a trade. They accept the universal understanding of it as a profession. Nor do they define "trade." They merely apply a rule of law. At most, such cases serve only to illustrate the development of a legal doctrine, having its origin in contracts concerning tradesmen, which became known as the doctrine "against restraint of trade," and which in course of time was extended and applied to agreements by doctors respecting their professional practice.

MUST FIND STATUTE SANCTION

The case of *Pratt v. Medical Association*, 1 K. B. 244, upon which the prosecution places much reliance, is interesting in the similarity of facts there proven and here alleged; yet the legal aspects differ greatly. The suit was a civil action in tort by the plaintiff doctors to recover damages for malicious injury to their means of livelihood. The claim was grounded upon common-law principles which hold every man liable in damages for wrongful injury to another's means of livelihood.

Combination was not the gist of the action; that circumstance only increased the damage. So here, if the livelihood of group practitioners has been injured by the wrongful acts of the defendants, they too have redress in a civil court. But the charge in the present case is criminal, and to stand must find its sanction solely in the statute.

Coming now to other specifications of the charge, one, two and five. Is the association, or are its members or the hospitals, engaged in trade within the meaning of section 3 of the statute? The association is alleged to be a nonprofit cooperative

association of government employees engaged in the business of arranging for the provision of medical care and hospitalization to its members and their dependents.

The plan and purpose, it is charged, was to hinder and obstruct the association in procuring and retaining on its staff qualified doctors; to hinder and obstruct its doctors from the privilege of consulting with others and using the facilities of the Washington hospitals, and to hinder and obstruct the association in obtaining access to hospital facilities for its members and its doctors from treating and operating upon their patients in the hospitals. The foregoing references to the Washington hospitals in the plan set forth forms the only support for the fifth specification, charging a purpose to restrain the business of operating said hospitals.

ADOPTED STORY DEFINITION

In previous discussion of the *Cleaners and Dyers' case* I have expressed the view that the Court in giving to the word "trade" its full meaning adopted the definition of Justice Story as its own. That definition covers both the narrow and broad understanding of the term. Its most restricted sense comprehended "traffic in goods or buying and selling in commerce or exchange." Manifestly, neither the association, its members or the hospitals are engaged in that sort of trade.

Nor do they, in my opinion, come within the broader class of manual or mercantile pursuits carried on for profit or gain without buying or selling goods. The business of the association was not of a manual or mercantile nature. It was a non-profit cooperative institution whose corporate object was to render service in providing medical and hospital care for its members. The argument for the government that the business of the cleaners and dyers involved merely the sale of service, and yet was held to be a trade, overlooks the fact that the very essence of that service was the skilful use of labor and material, quite equal to the "art, mystery or trade" of a tailor, blacksmith or shoemaker, mentioned by Justice Story in illustration of manual and mercantile pursuits falling within the category of trade.

Other federal and state decisions bear out the conception of trade as an occupation or pursuit of a mercantile character. See *Semler v. Board*, 294 U. S. 608; *Toxaway Hotel Co. v. Smathers & Co.*, 216 U. S. 439; *U. S. Hotel Co. v. Niles*, 134 Federal 235; *Harms v. Cohen*, 279 Federal 276 (as to musical composers); *People v. Klav*, 106 N. Y. S. 341 (as to the theater); *Metropolitan Co. v. Hammerstein*, 147 N. Y. S. 532 (as to grand opera); *Werch v. Co.*, 171 S. E. 255 (as to the insurance business); *Whitcomb v. Reid*, 31 Miss. 569 (as to dentistry), and *State v. McClellan*, 31 A. L. R. 527 (as to the laundry business).

POSITION HELD EXTREME

The thesis of government counsel taken from the opinion in *Brighton College v. Marriott*, 1 K. B. 312, 316, that "trade" embraces all who habitually supply "money's worth for full money payment" and their contention that the statute should be so broadly construed represents an extreme position which does violence to the common understanding of "trade," rejects authoritative decisions of our courts and ignores cardinal rules of statutory construction.

Their proposition encompasses all gainful work of the citizen. Can it be supposed if Congress had any such drastic intention it would not have made the purpose clear? Certainly it is not for the courts to stretch an old statute to fit new uses for which it was never intended. *United States v. Gradwell*, 243 U. S. 476, 488. That would be nothing short of "judicial legislation." The charge that members of the association were restrained (specification 2) is devoid of legal substance. Their efforts to obtain group medical care is expressed through the medium of the association, a corporate entity distinct from the individual members. Upon no theory can they be treated as engaged in the business of the corporation.

Finally, when the indictment is carefully studied in all its parts, each in relation to the others, it is difficult to escape the conclusion that in its substantial realities the scheme set forth directly centered upon various forms of restraint to be exerted against physicians in rendering treatment and care to their patients, and that all else is incidental to that design. If restraint upon doctors was the only real direct and immediate effect, any indirect effects upon the association or hospitals would not suffice to support the charges as to them. *Standard Oil Co. v. United States*, 283 U. S. 163, 179; *Nash v. United States*, 229 U. S. 373.

SUFFICIENCY OBJECTIONS

The defendants have raised objections to the sufficiency of the indictment as a pleading. These go mainly to the claim that many of the allegations dealing with essential and material

features of the charge are vague, indefinite and uncertain. The objections are far too numerous to deal with separately. There is merit to many of them. The indictment is afflicted with vague and uncertain statements. In some instances material facts are altogether lacking. An important instance concerns the charge that one purpose of the conspiracy was to restrain the business of the Washington hospitals.

The indictment is barren of any statement of the business methods used by a single hospital in the letting of its facilities and service to patients. This is fatal to that particular specification, for without such facts it cannot be known whether loss of patients through operation of the scheme would injuriously affect the economic welfare of any hospital.

Moreover, the particular plan and purpose of the conspiracy as respects the hospitals is only inferentially stated in that part which deals with the plan and purpose of the scheme as against the association and its doctors. Such a method of stating the material part of the charge does not meet the fundamental requirement that a criminal accusation be stated fully, clearly and with directness and certainty. *United States v. Hess*, 124 U. S. 483; *United States v. Geare*, 54 App., D. C. 30; *McMullen v. United States*, 68 App., D. C. 302.

INDIVIDUAL CHARGES QUESTIONED

A question also arises as to whether the charge is laid against the individual doctors named in the caption. This is due to the pleader's statement that they "will be referred to herein-after as the individual defendants," whereas thereafter the charge itself is laid only against "the defendants," who the caption indicates include only the several medical societies. It does seem that as to such simple, yet all-important matters, an indictment should be so drafted as to exclude any question whatever.

The inducement, as well as the charging part, setting forth the plan and purpose and acts done to effectuate the conspiracy, abound in uncertain statements. Inference, opinion and conjecture are also freely indulged. This is especially so in the inducement, much of which seems unnecessary to a statement of the charge. It is questionable whether some of it would be deemed relevant or competent in proof of the offense. Every indictment should be confined to a clear and dispassionate statement of essential fact. Thus, an accused can better know the exact offense with which he is charged and will not be confused in making his defense. Ordinarily improper matter in the inducement unnecessary to support the charges will not vitiate an indictment. It will be treated as surplusage and disregarded. But I doubt if such treatment would suffice to relieve these defendants of the prejudice likely to arise by an indictment which smacks so much of a highly colored, argumentative discourse against them. It must be remembered that when a case is finally submitted to a jury for their secret deliberations the indictment goes with them.

ILLEGAL OPERATION CONTENTION

The contention is made that the association is operating illegally in the fields of medicine and insurance; that as its activities are unlawful they do not come under the protection of the statute against restraints of trade. The indictment describes the association as a nonprofit, cooperative society, organized under the laws of the District of Columbia, engaged in the business of arranging for the provision of medical care and hospitalization to its members and their dependents on a risk-sharing prepayment basis. This is enough to indicate that it was organized under those sections of the general corporation laws providing for incorporation of societies for benevolent, charitable, educational, literary, musical, scientific or missionary purposes, including societies formed for mutual improvement or promotion of the arts. Thus, the view is strengthened that the association was not engaged in trade, for such corporate functions clearly would not fall under that category. However, I do not think it can be said from the bare allegations of the indictment, taken in their entirety, that the association is engaged in medical practice or insurance. Whether or not that is so could better be decided upon the evidence if in a trial it should be deemed pertinent to inquire into the question.

Finally, section 3 of the Sherman Act upon which the indictment is founded has been attacked by defendants as unconstitutional. It is argued that the statute is too vague and uncertain to fix a definite standard of guilt or inform one accused of violating it of the nature and cause of the accusation. I do not agree with the argument. If I did, the circumstances would not justify me declaring the statute invalid, for that would be unnecessary, hence inappropriate, in view of my holding that the indictment is bad on other grounds.

The several demurrers to the indictment are sustained. Judgment will be entered accordingly.

DEPARTMENT OF JUSTICE REPLIES

Press Release from the Department of Justice Commenting on Justice Proctor's Opinion

The Department of Justice will seek to reverse the decision handed down by Mr. Justice Proctor in the suit against the American Medical Association and others pending in the District of Columbia. This decision declares the indictment invalid on two grounds: First, that because of a restricted definition of the word "trade" in the Sherman Act, physicians are entitled to conspire with and boycott hospitals in order to exclude other members of their profession from the pursuit of their calling. Second, because the indictment does not inform the defendants of the crime with which they are charged.

The department makes this statement not for the purpose of criticizing the opinion but for the reason that it is important to inform physicians generally that, until the Supreme Court has acted, the government's prosecution policy toward boycotts in the medical profession is unchanged. None of the reasoning of the opinion persuades the department that doctors are free to engage in practices which would be illegal if they belonged to some other calling. In addition, any further restraints of the character included in the indictment will also be subject to prosecution. It is important that physicians not be misled on this point for the reason that the District Court opinion is not a binding authority on other judges.

The department, recognizing the seriousness of the present uncertain situation, will use every effort to get a final decision from the Supreme Court at the earliest possible moment.

The second ground for declaring the indictment invalid is that the defendants were not sufficiently informed of their offense. The department, without any criticism of the opinion, feels that the defendants were fully informed by the indictment of the nature of the offense and were at no time in the dark as to the character of the charges made against them. It will therefore seek an appeal on this count also.

The fact that the decision partly rests on this second ground complicates the appeal. In most antitrust proceedings it is possible for the government to appeal directly to the Supreme Court and thus obtain a more speedy final decision. Under the present circumstances, such a direct appeal is at least doubtful and the government may be forced to go first to an intermediate appellate court. It may be that, because of the delay occasioned by the doubt as to a direct appeal to the Supreme Court, time will be saved if a new grand jury is called to consider another indictment in a different technical form. However, even if this is done, an appeal will be presented at the same time. These technicalities, which in no way affect the merits of the case, must be carefully investigated. Therefore an announcement of the exact steps which will be taken by the government will be made within the next ten days.

PRESS COMMENT ON JUSTICE PROCTOR'S OPINION

OUR DOCTORS GO FREE

The Dayton (Ohio) Herald
July 27, 1939

In ruling that the American Medical Association has not violated and could not violate the Sherman Anti-Trust Act, the federal court of the District of Columbia has tossed out of court the most fantastic suit ever instituted by any government against its own people.

If the New Dealers in the so-called justice department ever studied American history, they should have remembered that famous phrase spoken in defense of American liberties by their great English champion, Edmund Burke: "I do not know the method of drawing up an indictment against a whole people." And if they remembered, they should have known that there is no law under which an honored profession can be indicted before a whole people.

This shocking insult to a free people by its own government, like many other ill conceived reforms, may have been rooted in good intentions. There is reason to believe that the practice of medicine should be changed in some respects to serve better the changing needs of the nation. There are too many people ill attended in sickness, just as there are too many people ill fed, ill clothed and ill housed. There is room for improvement in the practice of medicine as in every other field in this imperfect world.

But good intentions never excuse inexcusable tactics. If charges should be made, there are ways in which they should be made. Going at an entire profession with an upraised club and haling its members into court as lawbreakers is not one of them. Anyway, these smart young lawyers could have better started with another profession.

Who are these men charged with violating the laws of the land to be prosecuted by the people? They are, the vast majority of them, men who have dedicated their lives to the service of humanity. They have watched over the bedside of all of us, patted the breath of life into our bodies and will ease the pain when breath departs. They have sat beside us in the long night hours, and eyes opening from a fitful sleep have closed again in confidence because the doctor was there and would stay there as long as he was needed. They have seen to it that we got the medicines we needed, even when some of us could not pay for them. They have, in whatsoever house they entered, gone for the benefit of the sick and refrained from all wrongdoing and corruption.

These are the men who were haled into court, these men who have been healing the sick through the ages and making this a better world—haled into court by young upstarts who think they are going to make this a perfect world overnight. And the people who trust their doctors as they trust no one else are not going to forget or forgive. The suit was not only indefensible on ethical, moral and legal grounds; it was the worst sort of politics.

To be sure, there are doctors, just as there are lawyers, who violate the ethics of their profession, who are more interested in fees than in healing, who abuse their high calling. Most of us know a few of them and despise them. But lump them all together and weigh them in the scales against that doctor—a friendly, fun-loving old man, a kindly, serious-minded young man—who was not thinking of his fee when he gave of his time and his skill and his compassion in our hour of suffering, and he covers up a multitude of sins.

Dragging such men into court is high-handed and ridiculous.

NOT A TRADE

New York Herald Tribune
July 28, 1939

Judge Proctor's basic point in his decision for the American Medical Association and allied defendants in the antitrust action against them—namely, that the practice of medicine is not a trade in the meaning of the Sherman law—seems to us thoroughly sound both as law and as social policy. If the medical profession is not a learned profession then there is no such animal, and if our statutes aimed at the restraint of trade are not to discriminate between trade and the learned professions, then the attempts of the latter to create standards of admission and service must sooner or later go by the board.

On the other hand, this does not mean that a professional association is always right or just either in its interpretation of its code or in the measures of enforcement it takes. Judge Proctor's decision does not settle the question whether the defendants acted in a high-handed and indefensible manner toward the physicians in Washington engaged in group practice for the benefit of federal employees. An association, it will be remembered, was formed among employees of the Home Owners Loan Corporation to cooperate in providing medical care for its members and their dependents, engaging doctors for the purpose on a prepayment basis. The government contends that, prompted by officers of the American Medi-

cal Association, the local medical bodies instituted an active boycott against the experiment; that hospitals were closed to the cooperative's staff, that members of this staff who were also members of the local medical societies were either expelled or forced to resign their salaried positions on the staff; that specialists were forbidden to consult with those who remained, and so on. To all of which the defendants replied in substance that whatever discipline had been adopted was in pursuance of their right and duty to maintain the standards and ethics of the profession. Aware of the highly conservative tendencies of the A. M. A. and its local affiliates, and particularly of their traditional opposition to "socialized" medicine, the public would like to know whether the government's charges are true, and, if so, whether the acts complained of had real justification as a means of preventing malpractice or were provoked by prejudice.

We thoroughly agree with Judge Proctor that a criminal suit under the antitrust laws is not a proper method of bringing this out. He has suggested civil action by the aggrieved parties. Meanwhile, it should occur to the A. M. A. and its host of friends and sympathizers that even the appearance of a boycott in defense of political and social theories is something which in this country should be avoided like the plague.

BOOMERANG INDICTMENT

The Washington (D. C.) Post
July 27, 1939

The government's indictment of the American Medical Association and ancillary bodies has been turned into an indictment of the Department of Justice. Seldom has that law-enforcement agency suffered a sharper rebuke than that administered by Justice Proctor in District Court yesterday.

The rebuke is not softened by the general restraint of the court's comment on a silly suit, which Assistant Attorney General Thurman Arnold was most ill advised to initiate. Now, in the face of Justice Proctor's lucid and closely reasoned opinion, the Department of Justice is in an unenviable quandary. It must either admit that its indictment of the American Medical Association as a combination in restraint of trade was a blunder or it must take an appeal from a judgment which seems to leave very few footholds for effective criticism.

Such an appeal, if lost, would only further humiliate the administration and, win or lose, it would continue to exacerbate an issue which can only be solved by friendly cooperation. The A. M. A. and many of its subordinate bodies are now showing an unmistakable tendency to further, rather than impede, well managed group health projects. The Department of Justice will turn bad into worse if it stubbornly insists on pressing an indictment bound to arouse the strongest professional antagonism.

That indictment was characterized by Justice Proctor yesterday as a "highly colored, argumentative discourse." It was found by him to indulge freely in "inference, opinion and conjecture." The justice regarded it as "afflicted with vague and uncertain statements." The indictment, finally, was found lacking in "the fundamental requirement that a criminal accusation be stated fully, clearly and with directness and certainty."

These are biting criticisms of the government's case, entirely aside from the common-sense opinion, amply backed by legal precedent, that the practice of medicine cannot properly be defined as a "trade" in the sense intended by the antitrust laws. And while the criticisms are important for the case in point they are even more so as a demonstration of one of the cardinal and most vital principles of this democracy—the subordination of the government, just as much as that of the individual citizen, to the even-handed processes of law.

Justice Proctor's opinion yesterday will not be assessed at its true value unless its criticism of an obviously punitive action against the medical profession is emphasized. Unquestionably members of that profession have their shortcomings. Undoubtedly the attitude of some of them toward group health movements has been reactionary and socially injurious. But those mistakes are no excuse for an arbitrary attempt to dragoon organized medicine into lowering its cherished standards. To dictate in that manner, as Justice Proctor has ably indicated, the government must have a far better case than it was able to present.

BLOW TO REGIMENTATION

Ohio State Journal
July 27, 1939

New Deal efforts to regiment the medical profession sustained a crushing defeat in the decision of the federal district court at Washington, holding that the Sherman Anti-Trust Act could not apply to the practice of medicine. It was a decision that most people had felt was a foregone conclusion because it seemed a mistake in the first place to regard a learned, scientific profession as a trade.

The idea of prosecuting the profession, through suit against the American Medical Association, was born in the brain of Solicitor General Robert H. Jackson, who has shown on many occasions that he favors a form of government which, if not exactly totalitarian, certainly leans toward it to the extent that it would regiment important phases of our society. The suit was a silly idea in keeping with much that has come from the brain trust, but at no time was public opinion with the prosecution.

Rebuttal to the government claim that the medical association acted in restraint of trade was clear and to the point, when the A. M. A. spokesman averred that the organization had never opposed in policy or principle a well considered expanded program of medical service, when the need could be established. The meat of the whole question was in that rejoinder, for certainly the government could establish no need for the regimentation it demanded.

The verdict is a victory of the first magnitude, not only for the medical profession, but for the people as a whole, because it is a direct and smashing refusal of the courts to sustain regimentation in the U. S. A.

GOVERNMENT AND THE DOCTORS

The Chicago (Ill.) Daily News
July 31, 1939

The Federal Court of the District of Columbia dismissed the government's antitrust suit against the American Medical Association and allied medical bodies. If the government now insists upon taking its grievance against the doctors to a higher tribunal, then the government is what Mr. Beadle said the law was. Court proceedings ought never to have been instituted to determine, after months of hearings, something that should instantly have been arrived at by the application of elementary horse sense upon the part of the prosecution. It was a fantastic waste of the court's time and the taxpayers' money.

The court finds that doctors are not tradesmen, as that term is defined by the Sherman Act. Of course they are not. Every one with a grain of sense knows it. Every one knows that the framers of the Sherman law hadn't the slightest notion of including professional men within the scope of the act. Nearly every one knows also that our American medical men not only are among the world's most highly skilled, but among the most conscientious and tireless doers of good and disbursers of charitable service in this country. To charge such men with comprising a selfish trust, for the purpose of forestalling medical aid from those who need it, and enabling themselves to wax fat at the expense of the public, was utter, malicious tosh.

This is not to say that the doctors, or their associations, are perfectly free from error. It is not to say that government should not do all in its power to make medical and hospital care more readily available to people who now find them difficult to obtain. But government, in striving toward this admirable aim, will get nowhere by fighting and harassing the doctors. It must, rather, cooperate with them and seek their indispensable advice and aid.

The trust-busters, meanwhile, will do themselves, the doctors and the country a good turn by dropping this sorry matter right where it now stands. There are plenty of real trusts in America, plenty of actual enemies of our economic welfare, and plenty of demonstrable restraints upon the free flow of commerce that require the unsparing attention of these crusaders. Let them, therefore, get up against the real evils and stop wasting their energies and manpower—they are forever crabbing, by the way, about their shortage of personnel—on windmills.

A GRATIFYING DECISION—THE MEDICAL PROFESSION IS UPHELD

Columbus (Ohio) Dispatch
July 27, 1939

Although the government probably will appeal to higher courts, the decision of a federal district court at Washington yesterday that the practice of medicine is not limited by the Sherman Anti-Trust Law constitutes a valuable precedent and one which should weigh heavily in favor of this construction of the statutes when the case reaches a higher tribunal.

The department of justice had sought an indictment of the American Medical association and individual defendants, charging them with "restraint of trade" in opposing the activities of a cooperative health association in the District of Columbia. The ruling is to the effect that the practice of medicine is a learned profession, above and beyond the status of a commercial business or trade.

The decision does not necessarily mean that the work of group medicine organizations or cooperative enterprises, whereby members contract for medical service for an annual fee per person, is to be halted, nor that there is not a legitimate place for this sort of service for those who wish to take advantage of it. But it does mean that a bold attempt by the Roosevelt administration to summarily squelch opposition to a form of socialized medicine has been halted by the courts, which have so often during the nearly seven years of the New Deal rule proved to be the final barrier in defense of the people's rights and liberties. Carried to its ultimate conclusion, a decision favorable to the government might have been used as a basis for riding roughshod over all protests against the eventual socialization of medical practice on the grounds that it is a criminal violation of antitrust legislation.

The decision is soundly based. Medicine deals with the greatest of all issues—human life or death—and it cannot be limited or made subservient to the laws enacted to regulate merely commercial pursuits. The profession has a long and honorable tradition, rooted in a basic humanitarianism and self-sacrificing spirit which no hard-and-fast legal formula can define. There are admitted faults and inequities in the relationship of the medical profession in America to its 130,000,000 clients. But organized medicine is moving constructively and intelligently toward the solution of these problems and has been doing so without jeopardizing the highest grade of medical service and the best standards of research that obtain anywhere in the world today.

The time will come when better medical service will be available to more people at less cost. The medical profession recognizes this truth and is progressing steadily toward this goal on its own initiative. It is a goal which will be more fully realized if the meddling hand of politics is kept off the "noblest of the professions."

A. M. A. IN COURT

The New York Times
July 28, 1939

Most laymen will probably agree with at least one ground of the decision of Justice Proctor of the District of Columbia Federal Court dismissing the antitrust indictment against the American Medical Association. This is that, to apply the Sherman Act, forbidding restraint of trade, to the medical profession "represents an extreme position which does violence to the common understanding of the word 'trade.'" "To stretch an old statute to fit to new uses for which it was never intended," the court contends, "would be nothing short of judicial legislation."

The court dismisses the indictment also on the ground that it is indifferent and uncertain and lacking in material facts. But even though the A. M. A. has won a legal victory and even though it may hold it against a government appeal, the broader problem which led to the government's action remains. The American Medical Association cannot afford to oppose sincere efforts toward voluntary group action to provide adequate medical care for the needy. It is in its own interest, on the contrary, to cooperate actively to forward any plan which seems promising. Only the success of such voluntary group efforts is likely to prevent eventual resort to compulsory health insurance.

A 'LEARNED PROFESSION'

The Washington (D. C.) Evening Star
July 27, 1939

The practice of medicine is not a trade, according to Justice James M. Proctor of District Court. It is a "learned profession," as the American Medical Association has contended, and, as such, is beyond the purview of the Sherman Anti-Trust Act. By this interpretation of the law, the court—unless overruled by higher authority—has knocked the legal foundation from the charges brought by the federal government against the American Medical Association, the District Medical Society and other representatives of organized medicine. The corner stone of the government's case was the contention that physicians, in selling their services to the ailing, were tradesmen, within the meaning of the statute, just as patently as those who sell potatoes or who make automobiles. It was on this premise that a corps of special assistants to the Attorney General obtained from a special grand jury an indictment accusing the A. M. A. and certain affiliated societies and officers of conspiring to exercise "restraints of trade" against Group Health Association, Inc., local prepayment medical cooperative for federal employees.

Justice Proctor has thrown into sharper relief some of the legal issues involved in this unprecedented proceeding. Refer-

Cartoon in the Washington (D. C.) Evening Star
July 27, 1939

ring to the Supreme Court ruling cited in these columns last December, he held that the high court has excepted employment or business "in the liberal arts or in the learned professions" from the jurisdictional sphere of the Sherman Act. The practice of medicine, he pointed out, "admittedly" is one of the "learned professions." Carrying this reasoning further, he ruled that a grouping of professional men for the cooperative practice of medicine and for hospitalization of patients does not involve "manual or mercantile pursuits" within the meaning of the antitrust laws.

Justice Proctor has not, of course, settled the bitter controversy which has raged around the Group Health movement here and in other cities; nor has he brought to an end the battle in the courts between the aggressive Anti-Trust Division of the Department of Justice and the firmly entrenched forces of the A. M. A. and its co-defendants. Already the department has taken vigorous exception to the opinion and, in a public statement, has announced that federal attorneys are preparing to carry the fight to higher tribunals. It will be to the advantage of the physicians and the public as well to have the technical issues of antitrust jurisdiction in the field of medical practice finally resolved. And if the Supreme Court should send the case back to District Court for trial on its merits, that course, too, should be welcomed by the doctors named in the indictment—for only in that way will they have a fair chance to answer categorically in open court the serious imputations contained in the government's indictment which, if sustained, would have a far-reaching effect on organized medicine.

NOT A TRADE

The Baltimore (Md.) Sun
July 27, 1939

Justice Proctor in the District of Columbia Court has ruled that medical practice is not a trade within the meaning of the Sherman Anti-Trust Law. The ruling upsets the theory that the antitrust laws could be involved to break up an alleged medical monopoly and force the medical societies in Washington and everywhere else to recognize and even cooperate with ventures into the field of cooperative medical practice.

There have been doubts about this theory from the beginning. It was clear that the medical societies, including the American Medical Association, which was a defendant in the District of Columbia case, were not opposing cooperative

Oh, Most Upright Judge!

Cartoon in the Baltimore (Md.) Sun, July 27, 1939

medical ventures out of sheer greed. It was clear that they were thinking about their standards of professional ethics and that their idea was to prevent any arrangement from becoming general which would break down the close relation between patient and practitioner. To say, as the Department of Justice did in the suit which the District Court has now decided in favor of the defendant physicians, that refusal to sanction certain professional practices was a restraint of trade on the same level as a combination of merchants to fix prices was to stretch the antitrust laws far beyond their original intent and purpose. The court's refusal to indorse this interpretation shows that the original doubts were well founded.

It was unfortunate that Mr. Thurman Arnold, the Assistant Attorney General in charge of antitrust cases, chose to make the prosecution of the District of Columbia medical case the spearhead of the enlarged drive to enforce the Sherman Act to which he dedicated himself on coming to Washington. There is much to be said in favor of this campaign on general principles. Whether all of Mr. Arnold's many engaging theories about the antitrust laws are sound we cannot be sure.

But his activities as a trust buster have the merit of putting all those who may be inclined to ignore the laws against restraint of trade on notice that they cannot continue on their way with impunity. And it does emphasize the importance of competition in our economic life in a very promising way. But because this is so it does not follow that the extension of the antitrust laws to issues arising in the professional field was well advised. The ruling of the court against any such extensions seems to be sound sense as well as sound law.

MEDICOS EXONERATED

The Indianapolis (Ind.) Star
July 27, 1939

It was not surprising that a federal district court rejected the contention of the government that the American Medical Association's code of ethics and medical practice is a violation of the antitrust act. Counsel was upheld in the declaration that doctors are engaged in a "learned profession" rather than a trade and thus their activities are immune to provisions of the monopoly law.

Recent administration health proposals have been aimed at curbing the policies of organized medicine. Belief has been expressed that the New Dealers hope to establish a centralized, political bureaucracy controlling all activities of the medical profession. A more liberal public health program may modify some of the policies which heretofore have been stoutly defended by the A. M. A. and its subordinate state and local medical societies. That trend, however, should not be considered as implying current illegal, monopolistic practices on the part of organized medicine.

The present case resulted from charges by a group organized in the District of Columbia and supplying medical care for a flat monthly charge. That body alleged that the district medical society was discriminating against it through refusal of hospitals and doctors to receive patients referred by the group system. The Department of Justice obtained indictments against three medical organizations and twenty-one prominent physicians on the ground that they had conspired to restrain "trade."

Government counsel intimated that an appeal would be taken from the ruling of the district court. It is not easy to expect, however, that any court would interpret activities of the medical profession as coming within the scope of ordinary trade practices subject to provisions of the antitrust law.

'VAGUE' STATEMENTS

Washington (D. C.) Evening Star
July 28, 1939

In instituting criminal action under the Sherman Anti-Trust Act against the American Medical Association, the District Medical Society, the Harris County (Texas) Medical Society and various officials of those organizations, the Department of Justice proceeded under a provision of law which makes the antitrust statutes applicable within the confines of the District of Columbia, irrespective of whether interstate commerce is affected by the alleged restraints of trade. Government attorneys, before launching their fight against organized medicine, agreed that the battleground would have to be in Washington, for the difficulty of attempting to prove that the practice of medicine has interstate ramifications was conceded. In fact, the Attorney General's office, prior to launching the special grand jury proceedings that resulted in indictment of the A. M. A. and its aforementioned affiliates, announced that the investigation was confined solely to alleged "restraints of trade" against Group Health Association, Inc., within the District of Columbia. Published reports that the inquiry was to be extended into medical fields far beyond the District boundaries were denied, on the ground that the government had no jurisdiction.

It is somewhat surprising, and puzzling, therefore, to read that the department has issued a statement warning the medical profession at large that the decision of Justice James M. Proctor nullifying the indictment brought in the District of Columbia will not alter general plans for proceeding under the antitrust laws against physicians indulging in "boycotts." That other jurisdictions were in mind would seem to be implied by the

assertion that the opinion of the District Court "is not a binding authority on other judges." "It is important to inform physicians generally," the formal statement said, "that until the Supreme Court has acted, the government's prosecution policy toward boycotts in the medical profession is unchanged."

The attorney for the A. M. A. promptly retorted that the department's warning was "impertinent and unnecessary," adding that "as the (Anti-Trust) Division should know, the government has no jurisdiction whatever over the medical profession, save in the District of Columbia." Impertinent or not, the department's statement certainly is not consistent with its established policy nor with previous announcements from the Attorney General's office. It would seem to merit the same criticism which Justice Proctor applied to the indictment drawn up by representatives of the division. He said, among other things, that the indictment "is afflicted with vague and uncertain statements." It might not be "impertinent" to add that he also declared the indictment smacked of a "highly colored, argumentative discourse." Those are serious allegations, not likely to strengthen public confidence in the Anti-Trust Division at a time when the support of public opinion is deemed to be a valuable asset to the government in its commendable antimonopoly efforts.

SOUNDS LIKE GOOD LAW

Detroit (Mich.) *Free Press*
July 27, 1939

The ruling in which Judge James M. Proctor of the United States District Court in the District of Columbia says that the practice of medicine is a profession, not trade, and therefore is outside the scope of the antitrust laws sounds like good law and good sense.

The arguments with which the government undertook to support a contrary view in charging that the American Medical Association and fellow defendants have been guilty of "restraint of trade" within the provisions of the act did not sound like either.

They sounded like an effort to stretch the law in order to make it apply to a matter to which its makers never intended it should apply.

On this account the court ruling, which probably will be challenged by the government before the Supreme Court, is valuable.

Because preservation of the integrity of the spirit and intent of legislation is quite as important as preservation of its text.

Whether there is ground for complaint about the policies and acts of the defendants in the case just decided, on grounds outside those covered by laws and statutes, is, of course, an entirely different subject.

JUST AS EXPECTED

The Atlanta (Ga.) *Constitution*
July 27, 1939

The decision of a federal district court in the government's case against the American Medical Association, charging violation of the Sherman Anti-Trust Act, was but as expected. The court sustained a demurrer filed by the defense, finding that the A. M. A. and its joint defendants are not engaged in a "trade" as defined in the statute.

Thus, it is to be hoped, the court attack against the Medical Association comes to a much-to-be-desired close. There should be, if those in charge of the government case exercise reasonable wisdom, no appeal from the decision. The filing of the case, in the first place, was one of the most fantastic developments of a period of bureaucratic fantasy.

No one with a particle of knowledge concerning the medical profession, its ethics and the quality of the men engaged in its practice could conceive for a moment of any widespread conspiracy within its ranks, in contravention of the law of the land. That doctors, of all people, should be accused of operating a "trust" was, on its face, an absurdity.

There is little room for doubting that the healing professions have brought more unselfish sacrifice, more lasting benefit to the human race than any other. It is their mission to heal and, with rare exceptions, that is the enthusiasm of their life. Pecuniary reward is of minor interest to most physicians.

There is no denial that there is great need of increased medical service and increased hospitalization in this country. Too many sections are without doctors, too many American citizens can find no proper medical service in their need.

But this condition will be improved. It will be a slow and long process, toward the ideal medical provisions for the entire nation. One thing, however, is certain. It will only be reached with the cooperation of the healing professions. Without them, any such effort is foredoomed to failure.

Now that the unnecessary attack on the A. M. A. is apparently over, both sides to the argument should promptly forget and start anew toward the goal that both desire.

PROFESSION, NOT TRADE

Cleveland (Ohio) *Plain Dealer*
July 27, 1939

The Federal Court decision in the District of Columbia holding that practice of medicine is not a trade but a profession is in accord with common sense. From the termination of that distant era when the only surgeons were barbers and when the treatment for every ailment was to bleed the patient—from a vein rather than the pocketbook—the layman has recognized that fact. The American Medical Association takes the issue to the courts and the decision that the Sherman Anti-Trust Act does not apply to the practice of medicine results.

It is a victory for the medical profession. The prosecution contended that organizations and physicians had agreed to forbid group health doctors to practice in Washington hospitals, had refused consultations with them and had threatened them with expulsion from medical societies.

Group health and hospital insurance has been attacked on the grounds that it is an entering wedge for state or socialized medicine. Some have criticized public health agencies on the same basis. It is difficult to follow their course of reasoning. People will continue to select their physicians in the future as they have in the past. Summoning a doctor, except in cases of great emergency, never has been and probably never will be comparable to calling the police or fire department when there is a burglar or a blaze in the house. The personal relation that always has existed between ethical physician and patient should continue.

THE DOCTORS UPHELD

The Chicago (Ill.) *Tribune*
July 28, 1939

The indictment against the American Medical Association, a number of affiliated societies and twenty-one of their officers and members has been dismissed by United States District Judge James M. Proctor. A spokesman for the attorney general has said that an appeal will be taken.

The defendants had been charged with violating the antitrust laws. The judge said there could have been no violation because these laws are directed against conspiracies in business or trade, whereas the practice of medicine is a profession and therefore wholly outside the scope of the acts. Further than that, he found the indictments to be "afflicted with vague and uncertain statements," which "smacked of highly colored argumentative discourse."

The rebuke to the administration and its antitrust division was as sharp as it was merited. The tables have now been turned. The doctors have been acquitted of any intention to violate any law; the administration has been convicted of a conspiracy to abuse the law and its processes.

The indictments were obtained because the doctors, through their associations, had chosen not to fall in with the New Dealers' notions of the way in which medicine should be practiced. As usual, the administration could not tolerate dissent. There was no law which the attorney general could invoke against the doctors and, accordingly, the antitrust law was stretched out of shape to cover the alleged crime.

Perhaps it was thought that the medical societies and their members would lack the courage to fight and would accept a so-called consent decree rather than run the risk of fine and imprisonment. If so, the expectation was disappointed. The doctors refused to consider a shotgun decree, they did fight, and they won a victory which may hearten others in similar circumstances to stand on their rights and resist oppression.

AN ANALYSIS OF EXPENDITURES BY THE UNITED STATES GOVERNMENT FOR MEDICAL, HOSPITAL, HEALTH AND ALLIED SERVICES

The most commonly known branches of the federal government which require appropriations by the Congress for medical, hospital, health and allied services are the Public Health Service (formerly a part of the Treasury Department—now associated with the Social Security Board and other agencies in the Federal Security Agency), the Veterans' Administration and the Children's Bureau, Department of Labor. The extent to which other departments and independent establishments are engaged in medical, hospital, health and allied activities is not generally understood, and even a careful search of the Budget of the United States Government fails to reveal all the appropriations that are devoted to such activities. In many instances, some of the appropriations that are made for one department or establishment are transferred to another department or establishment for administration.

It becomes necessary, therefore, to consult many of the appropriation acts, the annual reports of some of the departments and independent establishments, and occasionally congressional committee hearings, for information not found in the budget on certain allotments of appropriations. Moreover, the appropriations for certain governmental agencies appear in the budget in such form that it is impossible to determine the amounts devoted to the medical, hospital or health phases of their activities. For example, the budget contains no actual expenditures or estimated appropriations for the colleges of medicine, dentistry or pharmacy, the University Health Service, social service or the graduate school activities in these fields under the appropriations listed for Howard University.

Discernible amounts for medical, hospital, health and allied purposes are listed in the budget of the United States under the following headings:

LEGISLATIVE BRANCH.

INDEPENDENT ESTABLISHMENTS:

- Civilian Conservation Corps.
- Civil Service Commission.
- Employees Compensation Commission.
- Federal Trade Commission.
- Railroad Retirement Board.
- Social Security Board.
- Works Progress Administration.
- Home Owners' Loan Corporation.
- Federal Housing Administration.
- Reconstruction Finance Corporation.
- Federal Emergency Administration of Public Works.
- Tennessee Valley Authority.
- Veterans' Administration.

DEPARTMENT OF AGRICULTURE:

- Office of the Secretary.
- Bureau of Animal Industry.
- Bureau of Plant Industry.
- Food and Drug Administration.

DEPARTMENT OF COMMERCE:

- Bureau of the Census.
- Bureau of Marine Inspection and Navigation.
- Bureau of Fisheries.

DEPARTMENT OF THE INTERIOR:

- Bureau of Indian Affairs.
- Government in the Territories.
- Saint Elizabeth Hospital for the Insane.

- Columbia Institution for the Deaf.
- Freedmen's Hospital.
- Howard University.

DEPARTMENT OF JUSTICE.

- Penal and Correctional Institutions.

DEPARTMENT OF LABOR:

- Office of the Secretary.
- Immigration and Naturalization Service.
- Children's Bureau.

NAVY DEPARTMENT:

- Office of the Secretary:
- Care of lepers, Island of Guam.

DEPARTMENT OF STATE:

- Medical aid for seaman.
- Pan American Sanitary Bureau.
- International Office of Public Health.
- Implementing the Narcotics Convention.
- Tenth Pan American Sanitary Conference.
- Ninth International Congress of Military Medicine and Pharmacy, Rumania.

TREASURY DEPARTMENT:

- Bureau of Narcotics.
- Public Health Service.

WAR DEPARTMENT CIVIL APPROPRIATION:

- Panama Canal.

DISTRICT OF COLUMBIA:

- Sewers.
- Health Department.
- Public Welfare.

The budgets of the United States government list amounts appropriated for purposes that are discernible as medical, hospital, health or allied activities aggregating the following totals for the years specified:

LEGISLATIVE BRANCH:

Actual expenditure, 1938.....	\$ 3,000
Appropriation estimate, 1939.....	3,500
Appropriation estimate, 1940.....	3,500

INDEPENDENT ESTABLISHMENTS:

Actual expenditure, 1937.....	\$ 69,435,762
Actual expenditure, 1938.....	156,443,556
Appropriation estimate, 1939.....	89,139,641
Appropriation estimate, 1940.....	78,934,511

REGULAR DEPARTMENTS AND DISTRICT OF COLUMBIA:

Actual expenditure, 1937.....	\$ 46,740,132
Actual expenditure, 1938.....	50,786,190
Appropriation estimate, 1939.....	53,457,983
Appropriation estimate, 1940.....	56,258,951

Totals discernible for legislative branch, independent establishments, regular department and District of Columbia:

Actual expenditure, 1937.....	\$116,175,894
Actual expenditure, 1938.....	207,229,746
Appropriation estimate, 1939.....	142,597,624
Appropriation estimate, 1940.....	135,193,462

The total combined expenditures and appropriations for the Departments of Commerce, Justice, Labor and State for the same period are listed in the budgets as follows:

Actual expenditure, 1937.....	\$134,182,222
Actual expenditure, 1938.....	124,325,876
Appropriation estimate, 1939.....	117,781,235
Appropriation estimate, 1940.....	149,407,496

When the amounts discernible for medical, hospital, health and allied purposes appropriated for the use of these departments are deducted, the totals are:

Actual expenditure, 1937.....	\$125,805,655
Actual expenditure, 1938.....	112,094,587
Appropriation estimate, 1939.....	107,223,468
Appropriation estimate, 1940.....	138,111,705
